# PROTEINS AND NUCLEIC ACIDS ENCODING SAME

### FIELD OF THE INVENTION

The invention generally relates to nucleic acids and polypeptides encoded thereby.

## BACKGROUND OF THE INVENTION

The invention generally relates to nucleic acids and polypeptides encoded therefrom. More specifically, the invention relates to nucleic acids encoding cytoplasmic, nuclear, membrane bound, and secreted polypeptides, as well as vectors, host cells, antibodies, and recombinant methods for producing these nucleic acids and polypeptides.

### SUMMARY OF THE INVENTION

2

The invention is based in part upon the discovery of nucleic acid sequences encoding novel polypeptides. The novel nucleic acids and polypeptides are referred to herein as NOVX, or NOV1, NOV2, NOV3, NOV4, NOV5, NOV6, NOV7, NOV8, NOV9, and NOV10 nucleic acids and polypeptides. These nucleic acids and polypeptides, as well as derivatives, homologs, analogs and fragments thereof, will hereinafter be collectively designated as "NOVX" nucleic acid or polypeptide sequences.

2

20

In one aspect, the invention provides an isolated NOVX nucleic acid molecule encoding a NOVX polypeptide that includes a nucleic acid sequence that has identity to the nucleic acids disclosed in SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, and 28. In some embodiments, the NOVX nucleic acid molecule will hybridize under stringent conditions to a nucleic acid sequence complementary to a nucleic acid molecule that includes a protein-coding sequence of a NOVX nucleic acid sequence. The invention also includes an isolated nucleic acid that encodes a NOVX polypeptide, or a fragment, homolog, analog or derivative thereof. For example, the nucleic acid can encode a polypeptide at least 80% identical to a polypeptide comprising the annino acid sequences of SEQ ID NOS:2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 27, and 29. The nucleic acid can be, for example, a genomic DNA fragment or a cDNA molecule that includes the nucleic acid sequence of any of SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 23, and 28.

25

Also included in the invention is an oligonucleotide, e.g., an oligonucleotide which includes at least 6 contiguous nucleotides of a NOVX nucleic acid (e.g., SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, and 28) or a complement of said oligonucleotide.

30

WO 02/33087 PCT/US01/32496

Also included in the invention are substantially purified NOVX polypeptides (SEQ ID NOS:2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 27, and 29). In certain embodiments, the NOVX polypeptides include an amino acid sequence that is substantially identical to the amino acid sequence of a human NOVX polypeptide.

The invention also features antibodies that immunoselectively bind to NOVX polypeptides, or fragments, homologs, analogs or derivatives thereof.

In another aspect, the invention includes pharmaceutical compositions that include therapeutically- or prophylactically-effective amounts of a therapeutic and a pharmaceutically-acceptable carrier. The therapeutic can be, e.g., a NOVX nucleic acid, a NOVX polypeptide,

10 or an antibody specific for a NOVX polypeptide. In a further aspect, the invention includes, in one or more containers, a therapeutically- or prophylactically-effective amount of this pharmaceutical composition.

In a further aspect, the invention includes a method of producing a polypeptide by culturing a cell that includes a NOVX nucleic acid, under conditions allowing for expression of the NOVX polypeptide encoded by the DNA. If desired, the NOVX polypeptide can then be recovered.

2

In another aspect, the invention includes a method of detecting the presence of a NOVX polypeptide in a sample. In the method, a sample is contacted with a compound that selectively binds to the polypeptide under conditions allowing for formation of a complex

between the polypeptide and the compound. The complex is detected, if present, thereby identifying the NOVX polypeptide within the sample.

The invention also includes methods to identify specific cell or tissue types based on

20

their expression of a NOVX.

Also included in the invention is a method of detecting the presence of a NOVX.

25 nucleic acid molecule in a sample by contacting the sample with a NOVX nucleic acid probe or primer, and detecting whether the nucleic acid probe or primer bound to a NOVX nucleic acid nucleule in the sample.

In a further aspect, the invention provides a method for modulating the activity of a NOVX polypeptide by contacting a cell sample that includes the NOVX polypeptide with a compound that binds to the NOVX polypeptide in an amount sufficient to modulate the activity of said polypeptide. The compound can be, e.g., a small molecule, such as a nucleic acid, peptide, polypeptide, peptidomimelic, carbohydrate, lipid or other organic (carbon containing) or inorganic molecule, as further described herein.

2 <del></del> muscle, bone, joint and skeletal disorders, hematopoietic disorders, uninary system disorders, response of cells to stimuli, Wiskott-Aldrich syndrome, cytoskeletal abnormalities, trauma, and disorders involving intercellular metabolic and electrical communication, diseases and growth and reproductive disorders, hypogonadism, fertility, and/or other pathologies and Osteoporosis, Ankylosing spondylilis, Scoliosis, Tendinitis, Dental disease and infection Tissue and organ transplantation, Fibromuscular dysplasia, Hyperparathyroidism, tissue regeneration (in vitro and in vivo), respiratory disease, gastro-intestinal diseases, involving maintainance of tissue homeostasis, growth control, development, and synchronized disorders involving coordination, proliferation and differentiation, diseases and disorders Hyperprolinemia, type II, erythrokeratodennia variabilis, palmoplantar keratoderma, discases deficiency, Bartter syndrome, type 3, Corneal dystrophy, crystalline, Schnyder, Hypophosphatasia (adult, childhood, infanlile), Porphyria cutanea larda, Porphyria, stationary, Pituitary ACTH-secreting adenoma, Elliptocytosis-1, Fucosidosis erythroderma, congenital, nonbullous, Long QT syndrome-3, Night blindness, congenital Hypoparathyroidism, Hyperthyroidism and Hypothyroidism, SIDS, Xerostomia, Tonsilitis hepatoerythropoielic, Schwartz-Jampel syndrome, Myopathy due to succinate dehydrogenase

The therapeutic can be, e.g., a NOVX nucleic acid, a NOVX polypeptide, or a NOVX-specific antibody, or biologically-active derivatives or fragments thereof.

disorders of the like.

of patients suffering from the diseases and disorders disclosed above and/or other pathologies and disorders of the like. The polypeptides can be used as immunogens to produce antibodies specific for the invention, and as vaccines. They can also be used to screen for potential agonist and antagonist compounds. For example, a cDNA encoding NOVX may be useful in yene therapy, and NOVX may be useful when administered to a subject in need thereof. By way of non-limiting example, the compositions of the present invention will have efficacy for treatment of patients suffering from the diseases and disorders disclosed above and/or other pathologies and disorders of the like.

The invention further includes a method for screening for a modulator of disorders or syndromes including, e.g., the diseases and disorders disclosed above and/or other pathologies and disorders of the like. The method includes contacting a test compound with a NOVX polypeptide and determining if the test compound binds to said NOVX polypeptide. Binding of the test compound to the NOVX polypeptide indicates the test compound is a modulator of activity, or of latency or predisposition to the aforementioned disorders or syndromes.

엉

Also within the scope of the invention is a method for screening for a modulator of activity, or of latency or predisposition to disorders or syndromes including, e.g., the diseases and disorders disolosed above and/or other pathologies and disorders of the like by administering at test compound to a test animal at increased risk for the aforementioned disorders or syndromes. The test animal expresses a recombinant polypeptide encoded by a NOVX nucleic acid. Expression or activity of NOVX polypeptide is then measured in the test unimal, as is expression or activity of the protein in a control animal which recombinantly-expresses NOVX polypeptide and is not at increased risk for the disorder or syndrome. Next, the expression of NOVX polypeptide in both the test animal and the control animal is compured. A change in the activity of NOVX polypeptide in the test animal relative to the control animal indicates the test compound is a modulator of latency of the disorder or syndrome.

S

2

2

In yet another aspect, the invention includes a method for determining the presence of or predisposition to a disease associated with altered levels of a NOVX polypeptide, a NOVX nucleic acid, or both, in a subject (e.g., a human subject). The method includes measuring the amount of the NOVX polypeptide in a test sample from the subject and comparing the amount of the polypeptide in the test sample to the amount of the NOVX polypeptide present in a control sample. An alteration in the level of the NOVX polypeptide in the test sample as compared to the control sample indicates the presence of or predisposition to a disease in the subject. Preferably, the predisposition includes, e.g., the diseases and disorders disclosed above and/or other pathologies and disorders of the like. Also, the expression levels of the new polypeptides of the invention can be used in a method to screen for various cancers as well as to determine the stage of cancers.

2

In a further aspect, the invention includes a method of treating or preventing a pathological condition associated with a disorder in a mammal by administering to the subject a NOVX polypeptide, a NOVX nucleic acid, or a NOVX-specific antibody to a subject (e.g., a human subject), in an amount sufficient to alleviate or prevent the pathological condition. In preferred embodiments, the disorder, includes, e.g., the diseases and disorders disclosed above and/or other pathologies and disorders of the like.

25

In yet another aspect, the invention can be used in a method to identity the cellular receptors and downstream effectors of the invention by any one of a number of techniques commonly employed in the art. These include but are not limited to the two-hybrid system, affinity purification, co-precipitation with antibodies or other specific-interacting molecules.

Other features and advantages of the invention will be apparent from the following

and examples are illustrative only and not intended to be limiting.

10 detailed description and claims.

## DETAILED DESCRIPTION OF THE INVENTION

The present invention provides novel nucleotides and polypeptides encoded thereby.

Included in the invention are the novel nucleic acid sequences and their encoded polypeptides.

The sequences are collectively referred to herein as "NOVX nucleic acids" or "NOVX polynucleotides" and the corresponding encoded polypeptides are referred to as "NOVX polypeptides" or "NOVX proteins." Unless indicated otherwise, "NOVX" is meant to refer to any of the novel sequences disclosed herein. Table A provides a summary of the NOVX nucleic acids and their encoded polypeptides.

NOVX nucleic acids and their encoded polypeptides are useful in a variety of applications and contexts. The various NOVX nucleic acids and polypeptides according to the invention are useful as novel members of the protein families according to the presence of domains and sequence relatedness to previously described proteins. Additionally, NOVX nucleic acids and polypeptides can also be used to identify proteins that are members of the family to which the NOVX polypeptides belong.

NOV1 is homologous to a Zinc Metalloprotease/ADAM-TS 7-like family of proteins.

S

congenital heart defeots, diabetes, diverticular disease, epilepsy, emphysema, endometriosis, example; adrenoleukodystrophy, Alzheimer's disease, autoimmune disease, allergies, the invention will be useful in therapeutic and diagnostic applications implicated in, for papillomavirus infection and cervical carcinoma, liver malignancies, skin disorders, inflammatory bowel disease, Lesch-Nyhan syndrome, leukodystrophies, multiple solerosis, purpura, immunodeficiencies, interstitial nephritis, IgA nephropathy, lymphaedema, (GVHD), growth and reproductive disorders, hemophilia, hypercoagulation, hypercalceimia endocrine dysfunctions, graft versus host disease, glomerulonephritis, graft versus host disease arteriosus, allergy, cerebral palsy, congenital adrenal hyperplasia, cirrhosis, cardiomyopathy, aertic stenosis, atrial septal defect (ASD), atrioventricular (A-V) canal defect, ductus addiction, auxiety, ataxia-tetangiectasia, asthma, ARDS, atherosclerosis, behavioral disorders, Thus, the NOV1 nucleic acids, polypeptides, antibodies and related compounds according to dystrophy, cerebral vascular disease, hypertension, cardiovascular disescases, renal disorders such as familial amyloidolic polymeuropathy, hyperkinelic diseases, muscular bacterial and viral infections, neonatal apnea, eagle's syndrome, atherosclerosis, metabolic ventricular septal defect (VSD), valve discases, Von Hippol-Lindau (VHL) syndrome, ulcers subaortic stenosis, transplantation, tuberous sclerosis, Von Hippel-Lindau (VHL) syndrome, Parkinson's disease, pain, polycystic kidney disease, pulmonary stenosis, pancreatitis, renal muscular dystrophy, myasthenia gravis, neurodegeneration, neuroprotection, obesity, Hunlington's disease, hypertension, hypogonadism, fertility, idiopathic thrombocytopenic artery stenosis, renal lubular acidosis, stroke, systemic lupus erythematosus, scleroderma, rheumatoid arthritis, or other pathologic or conditions. connective tissue disorders such as type VIIC Ehlers-Danros syndrome, osteoarthritis fibrogenesis, inflammatory bowel disease, Meckel syndrome, colorectal cancer,

5

WO 02/33087 · PCT/US01/32496

NOV2 is homologous to the Alpha-2-macroglobulin precursor-like family of proteins Thus NOV2 nucleic acids, polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in, for example, asthma, altergy and psoriasis, Alzheimer disease, Emphysema, pulmonary disease, immune disorders and Cancer and/or other pathologies and disorders.

S

NOV3 is homologous to a family of Heal Sodium/Bile Acid Cotransporter-like proteins. Thus, the NOV3 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in, for example: Primary bile acid malabsorption (PBAM, an idiopathic intestinal disorder), congenital diarrhea, steatorrhea, refractory infantile diarrhea, interruption of the enterohepatic circulation of bile acids, reduced plasma cholesterol levels, orohn's disease, Inflammatory bowel disease, Diverticular disease, Hirschsprung's disease, Cirrhosis, Transplantation, Hypercalceimia, Ulcers, growth failure and/or other pathologies.

NOV4 is homologous to the Prohibitin-like family of proteins. Thus, NOV4 nucleic acids, polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in, for example: breast cancer (In a sporadic breast cancer, Sato et al. (1992) found a missense mutation from valine (GTC) to alanine (GCC) at codon 88 of the PHB gene), and/or other pathologies.

NOV5 is homologous to the Macrophage Stimulating Protein Precursor-like family of 20 proteins. Thus NOV5 nucleic acids, polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in, for example: Aicardi-Goutieres syndrome I, Brugada syndrome, Deafness, autosomal recessive 6, Heart block, nonprogressive, Heart block, progressive, 2, Ichthyosiforme erythroderma, congenital, nonbullous, Long QT syndrome-3, Night blindness, congenital stationary, Pituitary ACTH-secreting adenoma, Small-cell cancer of lung, Ventricular fibrillation, idiopathic, entricular tachycardia, idiopathic, HIV infection, susceptibility/resistance to, Von Hippel-Lindau (VHL) syndrome, Cirrhosis, Transplantation, and/or other pathologics/disorders.

NOV6 is homologous to the Fatty Acid-Binding Protein-like family of proteins. Thus NOV6 nucleic acids, polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in, for example: Cardiomyopathy, Atherosclerosis, Hypertension, Congenital heart defects, Aortic stenosis, Atrial septal defect (ASD), Atrioventricular (A-V) canal defect, Ductus arteriosus, Pulmonary stenosis, Subaortic stenosis, Ventricular septal defect (VSD), valve diseases, Tuberous

chromsome 5 has 250 of 375 bases (66%) identical to a zinc metalloprotease ADAMTS6 databases include all GenBank databases and the GeneSeq patent database (ADAMTS6) mRNA from Homo supiens (GENBANK-ID: AF140674). Public nucleotide In a search of public sequence databases, the NOV la nucleic acid sequence, located on

indication of the probability that the aligned sequences could have achieved their similarity to cun "expect" to see just by chance when searching a database of a particular size. It decreases example, the probability that the subject ("Sbjct") retrieved from the NOV1 BLAST analysis, chance is 9.4e 25. The Expect value (E) is a parameter that describes the number of hits one the BLAST query sequence by chance alone, within the database that was searched. For e.g., thioredoxin mRNA from Ovis aries, matched the Query NOV1 sequence purely by Essentially, the E value describes the random background noise that exists for matches In all BLAST alignments herein, the "E-value" or "Expect" value is a numeric exponentially with the Score (S) that is assigned to a match between two sequences. between sequences.

ς.

2

reporting results. The default value used for blasting is typically set to 0.0001. In BLAST 2.0, in a database of the current size one might expect to see one match with a similar score simply matches. For example, an E value of one assigned to a hit can be interpreted as meaning that the Expect value is also used instead of the P value (probability) to report the significance of The Expect value is used as a convenient way to create a significance threshold for by chance. An E value of zero means that one would not expect to see any matches with a similar score simply by chance. See, e.g.,

~

will result from a BLAST search. This is a result of automatic filtering of the query for low-Low-complexity regions can result in high scores that reflect compositional bias rather than http://www.ncbi.nlm.nih.gov/Education/BLASTinfo/. Occasionally, a string of X's or N's complexity sequence that is performed to prevent artifactual hits. The filter substitutes any "NNNNNNNNNNNNNN") or the letter "X" in protein sequences (e.g., "XXXXXXXXXX"), significant position-by-position alignment. (Wootton and Federhen, Methods Enzymol low-complexity sequence that it finds with the letter "N" in nucleotide sequence (e.g., 266:554-571, 1996).

엉 subjected to the exon linking process to confirm the sequence. PCR primers were designed by silico predictions for the full length aDNA, part (one or more exons) of the DNA or protein suitable sequence that is either unique or highly selective was encountered, or, in the case of examined, walking inward from the respective termini toward the coding sequence, until a downstream sequence available for the reverse primer. In each case, the sequence was starting at the most upstream sequence available, for the forward primer, and at the most brain - thalamus, brain -whole, fetal brain, fetal kidney, fetal liver, fetal lung, heart, kidney, marrow, brain - amygdala, brain - cerebellum, brain - hippocampus, brain - substantia nigra, related human sequences sequences from other species. These primers were then employed in sequence of the target sequence, or by translated homology of the predicted exons to closely the reverse primer, until the stop codon was reached. Such primers were designed based on in redundancy. The resulting sequences from all clones were assembled with themselves, with gland, skeletal muscle, small intestine, spinal cord, spleen, stomach, testis, thyroid, trachea, lymphoma - Raji, mammary gland, pancreas, pituitary gland, placenta, prostate, salivary PCR amplification based on the following pool of human cDNAs: adrenal gland, bone the sequence reported below, which is designated NOV1c. This differs from the previously ESTs were included as components for an assembly when the extent of their identity with other fragments in CuraGen Corporation's database and with public ESTs. Fragments and uterus. Usually the resulting amplicons were gel purified, cloned and sequenced to high identified sequence NOV1a in having a different N-terminus another component of the assembly was at least 95% over 50 bp. In addition, sequence traces were evaluated manually and edited for corrections if appropriate. These procedures provide In the present invention, the target sequence identified previously, NOV1a, was

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 1K. In the ClustalW alignment of the NOVI proteins, as

٤

WO 02/33087 PCT/US01/32496

well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (i.e., regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

qni Ptam ptamols62, Pep\_Mi2B proper. Reprulysin family propertide. This region is the propertide for members of peptidase featury Mi2B. The propeptide contains a sequence motif similar to the "cysteine switch" of the matrixins. This motif is found at the C termins of the alignment but is not well aligned repeats. (SEQ ID NO:79) CO-learner but is not well aligned repeats. (SEQ ID NO:79) Score = 38:5 bits (88), Expect = 0.002

Thrombospondin-1 (THBS1) associates with the extracellular matrix and inhibits

ဂ္ဂ

anyjogenesis in vivo. In vitro, THBS1 blocks capitlary-like tube formation and endothetial cell proliferation. The antiangiogenic activity is mediated by a region that contains 3 type 1 (properdin or thrombospondin) repeats. By searching an EST database for sequences containing the antiangiogenic motif of THBS1, Vazquez et al. (1999) identified heart and lung cDNAs encoding ADAMTS1 and ADAMTS8, which they called METH1 and METH2, respectively. Sequence analysis predicted that the 890-annino acid ADAMTS8 protein shares 52% annino acid identity with ADAMTS1. ADAMTS8 is a secreted protein that has an N-terminal signal peptide, a zinc metalloprotease domain containing a zinc-binding site, and a

5

WO 02/33087

PCT/US01/32496

cysteine-rich region containing 2 putative disintegrin loops. The C terminus of ADAMTS8 has 2 heparin-binding thrombospondin repeats with 6 cys and 3 trp residues. Southern blot analysis showed that ADAMTS8 is a single-copy gene distinct from that encoding ADAMTS1. Northern blot analysis detected lighest expression of a 3.7-kb ADAMTS8 transcript in adult and fetal lung, with lower expression in brain, placenta, heart, and stomach, as well as fetal brain and kidney. Expression was also detected in a colon carcinoma cell linc. SDS-PAGE analysis demonstrated that ADAMTS8 is expressed as a 98-kD protein, a 79-kD protein after cleavage at the subtilisin site, or as a 64-kD protein, which is most abundant, generated by an additional processing event. Functional analysis determined that ADAMTS8

Ś

By interspecific backcross analysis, Georgiadis et al. (1999) mapped the mouse Adamts8 gene to chromosome 9 in a region showing homology of synteny with human 11q23-qter. They mapped the human ADAMTS8 gene to 11q25 by PCR analysis of a radiation hybrid mapping panel. The authors noted that a number of disorders have been mapped in the vicinity of the ADAMTS8 gene in mice and humans, most notably, given the expression and functional analyses, lung neoplasms.

2

disrupts angiogenesis in vivo and in vitro more efficiently than THBS1 or endostatin but

9

somewhat less efficiently than ADAMTS1.

The novel protein described here contains thrombospondin type I domains and Reprolysin domain. It is homologous to ADAM genes. Thrombospondin type I domain [IPR000884; (TSP1)] was found in the thrombospondin protein where it is repeated 3 times. Now a number of proteins involved in the complement pathway (properdin, C6, C7, C8A, C8B, C9) as well as extracellular matrix protein like mindin, F-spondin, SCO-spondin and even the circumsporozoite surface protein 2 and TRAP proteins of Plasmodium contain one or more instance of this repeat. It has been involved in cell-cell interraction, inhibition of angiogenesis, apoptosis. The intron-exon organisation of the properdin gene confirms the hypothesis that the repeat might have evolved by a process involving exon shuffling. A study of properdin structure provides some information about the structure of the thrombospondin type I repeat.

Reprolysin family propeptide [IPR002870; (Pep\_M12B\_propep)] domain is contained in the propeptide for members of peptidase family M12B. The propeptide contains a sequence molif similar to the 'cysteine switch' of the matrixins. This motif is found at the C terminus of the alignment but is not well aligned.

റ്റ

Through a subtractive hybridization approach to identify genes specifically expressed in the caput epididymidis, the mouse homologue of a member of the ADAM (a disintegrin and

ጟ

Chromosome 14, approximately 4-5 cM distal from the fertilin beta locus, which encodes mapping domonstrated that the ADAM7 gene maps to the central region of mouse castrate mouse did not show the apical localization of ADAM7 mRNA. Finally, chromosomal localization of ADAM7 mRNA is dependent upon an intact testis, because in situ manner, androgens as well as testicular factors for expression. Interestingly, the apical genetic strategies demonstrated that ADAM7 gene expression requires, in a region-dependent the epididymidis and to which no known function has been ascribed. Hormonal, surgical, and experiments revealed that the ADAM7 messenger RNA (mRNA) exhibited an apical expression in the twenty-six other tissues examined. Furthermore, in situ hybridization analyses demonstrated that the mouse ADAM gene, termed ADAM7, is expressed in the caput cell surface proteins that possess putative adhesion and protease domains. Northern blot another reproductive-specific ADAM protein (1). hybridization analyses of the proximal caput epididymidis from a testosterone maintained unusual sparsely granulated endoplasmic reticulum uniquely present in the proximal region of localization within the proximal caput epididynal epithelium that may correlate with an region of the epididymis and in the anterior pituitary gonadotropes with no detectable metalloprotoase) family of proteins was identified. This rapidly growing gene family encodes

5

S

sequence described here will have useful properties and functions similar to these genes Because of the presence of the domain and the homology to the, we anticipate that the

20

2

protein includes the nucleic acid whose sequence is provided in Table 1A, 1C, 1E, and 1G or modified bases, and nucleic acids whose sugar phosphate backbones are modified or functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic stability of the modified nucleic acid, such that they may be used, for example, as antisense include chemical modifications. Such modifications include, by way of nonlimiting example includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures that are complementary to any of the nucleic acids just described. The invention additionally whose sequences are complementary to those just described, including nucleic acid fragment still encoding a protein that maintains its ADAM-TS 7-like activities and physiological bases may be changed from the corresponding base shown in Table IA, 1C, IE and IG while acids, and their complements, up to about 33% percent of the bases may be so changed derivatized. These modifications are carried out at least in part to enhance the chemical The disclosed NOV1 nucleic acid of the invention encoding a ADAM-TS 7-like

13

ಚ

S 7-like activities and physiological functions, or a functional fragment thereof. In the mulant or variant protein, up to about 62% percent of the residues may be so changed shown in Table 1B, 1D, 1F, or 1H while still encoding a protein that maintains its ADAM-TS or variant protein any of whose residues may be changed from the corresponding residue whose sequence is provided in Table 1B, 1D, 1F, or 1H. The invention also includes a mutant The disclosed NOV1 protein of the invention includes the ADAM-TS 7-like protein

(Fab)2, that bind immunospecifically to any of the proteins of the invention. The invention further encompasses antibodies and antibody fragments, such as  $F_{ab}$  or

5 nucleic acids and proteins identified here may be useful in potential therapeutic applications protein (NOV1) may function as a member of a "ADAM-TS 7 family". Therefore, the NOV potential therapeutic applications for this invention include, but are not limited to: protein implicated in (but not limited to) various pathologies and disorders as indicated below. The therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug The above defined information for this invention suggests that this ADAM-TS 7-like

2 targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene and cell types composing (but not limited to) those defined here. delivery/gene ablation), research tools, tissue regeneration in vivo and in vitro of all tissues

2 ઝ 2 congenital heart defects, diabetes, diverticular disease, epilepsy, emphysema, endometriosis, arteriosus, allergy, cerebral palsy, congenital adrenal hyperplasia, cirrhosis, cardiomyopathy, aortic stenosis, atrial septal defect (ASD), atrioventricular (A-V) canal defect, ductus addiction, anxiety, ataxia-telangiectasia, asthma, ARDS, atherosclerosis, behavioral disorders, suffering from adrenoleukodystrophy, Alzheimer's disease, autoimmune disease, allergics, example, the compositions of the present invention will have efficacy for treatment of patients may be useful when administered to a subject in need thereof. By way of nonlimiting protein (NOVI) may be useful in gene therapy, and the ADAM-TS 7 -like protein (NOVI) and disorders as indicated below. For example, a cDNA encoding the ADAM-TS 7-like therapeutic applications implicated in cancer including but not limited to various pathologies (GVHD), growth and reproductive disorders, hemophilia, hypercoagulation, hypercalceimia muscular dystrophy, myasthenia gravis, neurodegeneration, neuroprotection, obesity, inflammatory bowel disease. Lesch-Nyhan syndrome, lenkodystrophies, multiple sclerosis, purpura, immunodeficiencies, interstitial nephritis, IgA nephropathy, lymphacdema, Hunlington's disease, hypertension, hypogonadism, fertility, idiopathic thrombocytopenic endocrine dysfunctions, graft versus host disease, glomerulonephritis, graft versus host disease The NOV1 nucleic acids and proteins of the invention are useful in potential

Parkinson's disease, pain, polycystic kidney disease, pulmonary stenosis, pancreatitis, renal artery stenosis, renal tubular acidosis, strokc, systemic lupus erythematosus, scleroderma, subaortic stenosis, renal tubular acidosis, strokc, systemic lupus erythematosus, scleroderma, subaortic stenosis, Iransplantation, tuberous sclerosis, Yon Hippel-Lindau (VHL) syndrome, ulcers, bacterial and viral infections, neonatal apnea, eagle's syndrome, alherosclerosis, metabolic disorders such us familial amyloidotic polyneuropalhy, hyperkinetic diseases, muscular dystrophy, cerebral vascular disease, hypertension, cardiovascular diseases, renal fibrogenesis, inflammatory bowel disease, Meckel syndrome, colorectal cancer, papillomavirus infection and cervical carcinoma, liver malignancies, skin disorders, connective tissue disorders such as type VIIC Ehlers-Danros syndrome, osteoarturitis, rheumatoid arthritis, or other pathologie or conditions. The NOV1 nucleic acid encoding the ADAM-TS 7-like protein of the invention, or fragments thereof, may further be useful in diagnostic applications, wherein the presence or amount of the nucleic acid or the protein are to be assessed.

9

2

2

NOV Ic protein has multiple hydrophilic regions, each of which can be used as an immunogen. NOV1 nucleic acids and polypeptides are further useful in the generation of antibodies art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" acids 280 to 320, from about amino acid 350 to 400, from about amino acid 420 to 470, from which can be used as an immunogen. In one embodiment, a contemplated NOV1d epitope is section below. The disclosed NOV Ia and b proteins have multiple hydrophilic regions, each epitope is from about amino acids 20 to 70. In another embodiment, a NOV1a and b epitope is from about amino acids 80 to 180. In additional embodiments, NOV1a and b epitopes are about amino acid 480 to 620, from about amino acid 700 to 750, and from about amino acids diagnostic methods. These antibodies may be generated according to methods known in the of which can be used as an immunogen. In one embodiment, a contemplated NOV la and b acid 400 to 530, from about amino acid 540 to 550, from about amino acid 580 to 610, from from about amino acids 20 to 180. In another embodiment, a NOV1d epitope is from about from about amino acids 200 to 280, from about amino acids 300 to 360, from about amino In one embodiment, a contemplated NOV Ic epitope is from about amino acids 1 to 50. In another embodiment, a NOV1c epitope is from about amino acids 80 to 100. In additional embodiments, NOV1c epitopes are from about amino acids 110 to 260, from about amino about amino acid 630 to 680, and from about amino acids 710 to 750. Also, the disclosed 770 to \$10. Also, the disclosed NOV1d protein has multiple hydrophilic regions, each of that bind immuno-specifically to the novel NOV1 substances for use in therapeutic or

3

2

WO 02/33087 PCT/US01/32496

amino acids 190 to 280. In additional embodiments, NOV1d epitopes sre from about amino acids 300 to 360, from about amino acids 300 to 360, from about amino acid 580 to 610, from about amino acid 580 to 610, from about amino acid 580, and from about amino acids 710 to 750. These novel proteins can be used in assay systems for functional analysis of

5 various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

### NOV2

A disclosed NOV2 nucleio acid of 4488 nucleotides (also referred to as SC\_78316254\_A) encoding a novel alpha-2-macroglobulin precursor-like protein is shown in Table 2A. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 1-3 and ending with a TGA codon at nucleotides 4477-4479. A putative untranslated region upstream from the initiation codon and downstream from the termination codon is underlined in Table 2A, and the start and stop codons are in bold letters.

2

## Table 2A, NOV2 nuclcotide sequence (SEQ ID NO:9).

The disclosed NOV2 nucleic acid sequence, localized to chromsome 12, has 840 of 1324 bases (63%) identical to a *Rattus norvegicus* Alpha-2-Macroglobulin Precursor mRNA (GENBANK-ID: RATA2M) (E = 1.3c<sup>-119</sup>).

S

A NOV2 polypeptide (SEQ ID NO:10) encoded by SEQ ID NO:9 has 1492 amino acid residues and is presented using the one-letter code in Table 2B. Signal P, Psort and/or Hydropathy results predict that NOV2 does contain a signal peptide and is likely to be localized extracellularly with a certainty of 0.3703. In other embodiments, NOV2 may also be localized to the lysosome (lumen) with a certainty of 0.1900, the microbody (peroxisome) with a certainty of 0.1585, or the endoplasmic reticulum (membrane) with a certainty of 0.1000. The most likely cleavage site for a NOV2 peptide is between amino acids 17 and 18, al: A1A-EE.

5

The proteinase-binding alpha-macroglobulins (A2M) [1] are large glycoproteins found 15 in the plasma of vertebrates, in the hemolymph of some invertebrates and in reptiliun and avian egg white. A2M-like proteins are able to inhibit all four classes of proteinases by a 'trapping' mechanism. They have a peptide stretch, called the 'bait region', which contains specific cleavage sites for different proteinases. When a proteinase cleavos the bait region, a conformational change is induced in the protein, thus trapping the proteinase. The entrapped enzyme remains active against low molecular weight substrates, whilst its activity toward larger substrates is greatly reduced, due to steric hindrance. Following cleavage in the bait region, a thiol ester bond, formed between the side chains of a cysteine and a glutamine, is cleaved and mediates the covalent binding of the A2M-like protein to the proteinase.

Alpha2-Macroglobulin (A2M) is a proteinase inhibitor found in association with senile plaques (SP) in Alzheimer's disease (AD). A2M has been implicated biochemically in binding and degradation of the amyloid beta (Abeta) protein which accumulates in SP. We studied the relationship between Alzheimer's disease and a common A2M polymorphism, Val1000 (GTC)/Ile1000 (ATC), which occurs near the thiolester active site of the molecule. In an initial exploratory data set (90 controls and 171 Alzheimer's disease) we noted an inorcased frequency of the Cl/G genotype from 0.07 to 0.12. We therefore tested the hypothesis that the Gl/G genotype is over-represented in Alzheimer's disease in an additional independent data set: a group of 339 controls and 566 Alzheimer's disease patients. In the hypothesis testing cohort,

Fisher's exact test). The odds ratio for Alzheimer's disease associated with the G/G genotype was 1.77 (1.16-2.70, P < 0.01) and in combination with APOE4 was 9.68 (95% CI 3.91-24.0, P < 0.001). The presence of the G allele was associated with an increase in Abeta burden in a small series. The A2M receptor, A2M-r/LRP, is a multifunctional receptor whose ligands include apolipoprotein E and the amyloid precursor protein. These four proteins have each been genetically linked to Alzheimer's disease, suggesting that they may participate in a common disease pathway.

he G/G genotype increased from 0.07 in controls to 0.12 in Alzheimer's disease (P < 0.05,

WO 02/33087

and, therefore, may confer specific proleinase recognition capabilities on rat alpha 2coded for by a 4790 +/- 40 nucleotide messenger RNA. It contains a typical internal thiol ester produced from rats undergoing acute inflammation. The coding sequence for rat alpha 2macroglobulin. Following an inflammatory stimulation, rat alpha 2-macroglobulin mRNA corresponding to 29 and 11% identity, respectively. These areas are located in the bait region share 73% identity, two small divergent areas of 17 and 38 residues were found macroglobulin. Although the amino acid sequences of rat and human alpha 2-macroglobulin region and 25 cysteine residues which are conserved between rat and human alpha 2nontranslated regions were determined. The mature protein consisting of 1445 amino acids is macroglobulin including its 27-residue signal peptide and the 3' - and parl of the 5' increased transcription rates and post-transcriptional processing. suggest that the accummulation of alpha 2M mRNA is due to the combined effects of fold increase in nuclei from acutely inflamed rats as compared to controls. These results alpha 2-macroglobulin gene as measured in nuclear run-on experiments showed a less than 3levels had decreased to less than 30% of the maximum value. Transcription rates from the levels increased 214-fold over control values and reached a maximum at 18 h. By 24 h the Six alpha 2-macroglobulin cDNA clones were isolated from two liver cDNA libraries

and a 39-kDa associated protein. Previous studies have established that the 515/85-kDa components are derived from a 600-kDa precursor whose complete sequence has been chromatography contains three polypeptides: a 515-kDa heavy chain, an 85-kDa light chain, cDNA cloning. The deduced amino acid sequence contains a putative signal sequence that determined by cDNA cloning (Herz, J., Hamann, U., Rogne, S., Myklebost, O., Gassepohl, H., precedes the 323-residue mature protein. Comparative sequence analysis revealed that alpha structure of the human 39-kDa polypeptide, termed alpha 2M receptor-associated protein, by and Stanley, K. (1988) EMBO J. 7,4119-4127). We have now determined the primary experiments revealed that the newly formed alpha 2M, receptor-associated protein remains apolipoprotein E containing the low density lipoprotein receptor binding domain. Pulse-chase region of alpha 2M receptor-associated protein has 26% identity with a region of portion of gp 330, is in fact a distinct protein. Further, the 120-residue carboxyl-terminal interspecies homologues and indicates that the pathogenic domain, previously thought to be a protein termed HBP-44. The high overall identity suggests that these molecules are domain of Heymann nephritis antigen gp 330 and 77% identity to a mouse heparin-binding 2M receptor-associated protein has 73% identily with a rat protein reported to be a pathogenic The alpha 2-macroglobulin (alpha 2M) receptor complex as purified by affinity

cell-associated, while surface labeling experiments followed by immunoprecipitation suggest that this protein is present on the cell surface forming a complex with the alpha 2M receptor heavy and light chains.

Alpha-2-macroglobulin is a serum pan-protease inhibitor. A possible correlation to this gene is the following reference on Rhinovirus infections causing exacerbations of cosinophilic airway disease. The acute effects of allergen-challenge on nasal interleukin-8 (IL-8), eosinophilic airway disease. The acute effects of allergen-challenge on nasal interleukin-8 (IL-8), eosinophilic cationic protein (ECP), and alpha2-macroglobulin were examined in atopic subjects with common cold symptoms. Twenty-three patients with seasonal allergic rhinitis were inoculated with human rhinovirus 16 outside the pollen season. Diluent and allergen challenges, followed by nasal lavages, were carried out about 3 months before and 4 days after virus inoculation. Seventeen patients developed significant common cold symptoms with

increased nasal lavage fluid levels of alpha2-macroglobulin, IL-8, and ECP at baseline (p<0.001-0.05 versus before inoculation), and were further increased by allergen challenge (p<0.001-0.05); IL-8 and BCP levels were correlated. See *Eur Respir J* 1999 Jan; 13(1):41-7.

Allergen challenge-induced acute exudation of IL-8, ECP and alpha2-macroglobulin in human rhinovirus-induced common colds. Greiff L, Andersson M, Svensson C, Linden M, Myinf S, Persson CG Dept of Otorhinolaryngology, Head and Neck Surgery, University Hospital, Lund.

In the CNS areaAlpha-2-macroglobulin has been implicated in Alzheimer disease

(AD) based on its ability to mediate the clearance and degradation of A-beta, the major
component of amyloid beta deposits. Blacker et al. (1998) analyzed a deletion in the A2M
gene at the 5-prime splice site of exon IF of the bait region (exon 18) and found that
inheritance of the deletion, designated A2M-2, conferred increased risk for AD.

The disclosed NOV2 nucleic acid of the invention encoding a Alpha-2-macroglobulin precursor-like protein includes the nucleic acid whose sequence is provided in Table 2A or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 2A while still encoding a protein that maintains its Alpha-2-macroglobulin precursor-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or

ಜ

ឧ

acids 110 to 200. In additional embodiments, NOV2 epitopes are from about amino acids 290 art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" NOV2 nucleic acids and polypeptides are further useful in the generation of antibodies about amino acids 1190 to 1210, from about amino acids 1240 to 1320, and from about amino acids 1400 to 1450. These novel proteins can be used in assay systems for functional analysis of various human disorders, which are useful in understanding of pathology of the disease and that bind immunospecifically to the novel substances of the invention for use in therapeutic or diagnostic inethods. These antibodies may be generated according to methods known in the section below. The disclosed NOV2 protein has multiple hydrophilic regions, each of which about annino acids 80 to 100. In another embodiment, a NOV2 epitope is from about amino can be used as an immunogen. In one embodiment, a contemplated NOV2 epitope is from to 340, from about 380 to 400, from about amino acids 410 to 580, from about amino acids 620 to 730, from about amino acids 810 to 900, from about amino acids 990 to 1100, from development of new drug targets for various disorders. 8

WO 02/33087

PCT/US01/32496

The disclosed NOV3 amino acid has 129 of 331 amino acid residues (38%) identical to, and 198 of 331 amino acid residues (59%) similar to, the 348 amino acid residue iteal sodium/bite acid cotransporter protein from *Cricetulus griseus* (Chinese hamster) (Q60414) (E= 1.6c<sup>.36</sup>).

The NOV3 sequence is predicted to be expressed in ileum because of the expression pattern of (GENBANK-ID: NTCI\_HUMAN) a closely related ILEAL SODIUM/BILE ACID COTRANSPORTER homolog in species *Homo sopiem*.

TaqMan data for NOV3 can be found below in Example 2. NOV3 also has homology to the annino acid sequences shown in the BLASTP data listed in Table 3E.

Bile acids are synthesized from cholesterol in the liver and secreted into the small intestine, where they facilitate absorption of fat-soluble vitamins and cholesterol. Wong et al. (1996) noted that, rather than being exoreted, the majority of bile acids are reabsorbed from the intestine and returned to the liver via the portal circulation. In the liver, bile acids are quantitatively extracted and resecreted into bile, thereby eliminating the need for substantial do novo hepalic bile acid synthesis. The ileum is the najor site of active uptake of bile acids from 185 the intestine, where the sodium-gradienl-driven transporter has been identified in the iteal enterocyte. Mutations in the transporter or other ileal genes that participate in the transport of bile acids are predicted to affect bile acid and cholesterol metabolism significantly. For example, Heubi et al. (1982) described an apparent familial defect in active ileal bile acid transport.

Using homologous sequences from hamster and rat, Wong et al. (1995) cloned a cDNA encoding an ileal sodium/bite acid cotransporter gene (designated ISBT by them). They also isolated a genomic clone for human ISBT. The gene encodes a 348-amino acid polypeptide with 7 predicted transmembrane domains and a predicted molecular mass of 38 kD. The native human protein has a relative molecular mass of 40 kD on SDS gcl electrophoresis due to N-linked glycosylation. Wong et al. (1995) demonstrated a dysfunctional mutation (P290S) in the iteal sodium-bite acid cotransporter gene in the course of cloning the human cDNA.

S

Wong et al. (1996) mapped the SLC10A2 gene to chromosome 13 by study of a human/rodent cell hybrid mapping panel and refined the localization to 13q33 by fluorescence in situ hybridization. The ileal sodium-bile acid cotransporter gene is clearly distinct from the hepatic sodium-bile acid cotransporter gene (SLC10A1; 182396) which maps to chromosome 14. Lammert et al. (1998) mapped the Slo10a2 gene to mouse chromosome 8 in a region homologous to chromosome 13q33.

5

missense mutations at conserved amino acid positions, L243P and T262M (601295.0001). In mutation and a mutated donor splice site for exon 3 (601295.0002). The other allele encoded 2 PBAM-associated mutations using SSCP analysis. Four polymorphisms were identified and and reduced plasma cholesterol levels. Oelkers et al. (1997) screened the SLC10A2 gene for with congenital diarrhea, steatorrhea, interruption of the enterohepatic circulation of bile acids control subjects, whereas the A171S was present in 28% of that population. The findings of on taurocholate uptake. The dysfunctional mutations were not detected in 104 unaffected transporter protein expression or trafficking to the plasma membrane; however, transport of transfected COS cells, the L243P, T262M, and double mutant (L243P/T262M) did not affect sequenced in a family with congenital PBAM. One allele encoded an A171S missense the iteal Na(+)/bite acid cotransporter's role in intestinal reclamation of bite acids. Autosomal Oelkers et al. (1997) established that SLC 10A2 mutations can cause PBAM and underscored taurocholate and other bile acids was abolished. In contrast, the A171S mutation had no effec SLCSA1 (182380), the cotransporter defective in glucose/galactose malabsorption. the L243P and T262M missenso mutations, was free of clinical symptoms. The authors stated supported by the findings that the proband's son, who inherited an SLC10A2 allele encoding recessive inheritance had been suggested by earlier studies of PBAM patients and was this was the second reported defect of a Na(+)/solute cotransporter, the first having been Primary bile acid malabsorption (PBAM) is an idiopathic intestinal disorder associated As reviewed by Small (1997), the enterohepatic circulation (EHC) is an in vivo

suggest that NOV3 may have important structural and/or physiological functions characteristic wherein the presence or amount of the nucleic acid or the protein are to be assessed, as well as molecule drug target, (iii) an antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), (iv) a nucleic acid useful in gene therapy (gene delivery/gene ablation), and (v) a serving as a specific or selective nucleic acid or protein diagnostic and/or prognostic marker, potential therapeutic applications such us the following: (i) a protein therapeutic, (ii) a small The protein similarity information, expression pattern, and map location for the Ileal Sodium/Bile Acid Cotransporter-like protein and nucleic acid (NOV3) disclosed herein of the citron kinase-like family. Therefore, the NOV3 nucleic acids and proteins of the invention are useful in potential diagnostic and therapeutic applications. These include composition promoting tissue regeneration in vitro and in vivo.

25

30

The NOV3 nucleic acids and proteins of the invention are useful in potential diagnostic and therapeutic applications implicated in various diseases and disorders described below. For

57

example, the compositions of the present invention will have efficacy for treatment of patients congenital diarrhea, steatorrhea, refractory infantile diarrhea, interruption of the enterohepatic suffering from Primary bile acid malabsorption (PBAM, an idiopathic intestinal disorder), circulation of bile acids, reduced plasma cholesterol levels, crohn's disease, Inflammatory

4yperculceimia, Ulcers, growth failure and/or other pathologies. The NOV3 nucleic acid, or fragments thereof, may further be useful in diagnostic applications, wherein the presence or bowel disease, Diverticular disease, Hirschsprung's disease, Cirrhosis, Transplantation, imount of the nucleic acid or the protein are to be assessed.

art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" NOV3 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immunospecifically to the novel substances of the invention for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the section below. For example the disclosed NOV3 protein have multiple hydrophilic regions, each of which can be used as an immunogen. In one embodiment, contemplated NOV3 2

about amino acids 55 to 60. In additional embodiments, NOV3 epitopes are from about amino ooids 140 to 150, from about amino acids 180 to 190, and from about amino acids 280 to 330. epitope is from about amino acids 5 to 30. In another embodiment, a NOV3 epitope is from analysis of various human disorders, which will help in understanding of pathology of the This novel protein also has value in development of powerful assay system for functional disease and development of new drug targets for various disorders. 2

### NOV4

ನ

reading frame was identified beginning with an ATG initiation codon at nucleotides 6-8 and ending with a TGA codon at nucleotides 822-824. A putative untranslated regions upstream A disclosed NOV4 nucleic acid of 850 nucleotides (designated CuraGen Acc. No. AL161453\_A) encoding a novel Prohibitin -like protein is shown in Table 4A. An open

25

of the initiation codon and downstream from the termination codon are underlined in Table

4A, and the start and stop codons are in bold letters.

Table 4A. NOV4 Nucleotide Sequence (SEQ ID NO:13)

The nucleic acid sequence of NOV4, localized on chromosome 9, has 782 of 849 bases (92%) identical to a Prohibitin mRNA from *Homo sapiens* (GENBANK-ID: S85655) (E = 7.2e<sup>-158</sup>).

S

A NOV4 polypeptide (SEQ ID NO:14) encoded by SEQ ID NO:13 is 272 amino acid residues and is presented using the one letter code in Table 4B. Signal P, Psort and/or Hydropathy results predict that NOV4 has a signal peptide and is likely to be localized at the endoplasmic reticulum (membrane) with a certainty of 0.5500. In other embodiments, NOV4 may also be localized to the lysosome (lumen) with a certainty of 0.2631, the endoplasmic reticulum (lumen) with a certainty of 0.1000, or extracellularly with a certainty of 0.1000. The most likely cleavage site for a NOV4 peptide is between amino acids 25 and 26, at: VNS-AL.

5

Genes that negatively regulate proliferation inside the cell are of considerable interest because of the implications in processes such as development and cancer. Prohibitin, a novel cytoplasmic anti- proliferative protein widely expressed in a variety of tissues, inhibits DNA synthesis. Studies have suggested that Prohibitin may be a suppressor gene and is associated with tumor development and/or progression of at least some breast cancers. Sequence 2

comparisons suggest that the Prohibitin gene is an analogue of Cc, a Drosophila gene that is vital for normal development. 2

Prohibitin gene and mapped it to 17q12-q21 by in situ hybridization. Sato et al. (1993) showed Prohibitin is a 30-kD intracellular, antiproliferative protein. White et al. (1991) mapped determined that the PHB gene was located in the 17q11.2-q23 region. By in situ hybridization, the gene to chromosome 17 by analysis of human-mouse somatic cell hybrid cell lines using a genomic fragment of human Prohibitin DNA isolated from a library using the rat Prohibitin cDNA clone. By a study of cell lines containing portions of human chromosome 17, they they localized the gene to 17q21. Sato et al. (1992) isolated the human homolog of the rat that the human Prohibitin gene family consists of 1 functional PHB gene on 17q21 and 4 processed pseudogenes, each on a different chromosome: PHBP1 on 6q25, PHBP2 on 25 8

lhey identified 4 cases of somatic mutation: 2 of these were missense mutations, 1 showed a 2bp deletion resulting in truncation of the gene product due to frameshift, and the fourth had a By DNA sequence analysis of 2 exons in the PHB gene in 23 sporadic breast cancers that showed loss of heterozygosity on 17q or developed in patients 35 years old or younger, 11p11.2, PHBP3 on 1p31.3, and PHBP4 on 2q21.

33

C-to-T transition in an intron adjacent to an intron-exon boundary. Sato et al. (1993) found no mutations in the PHB gene in other forms of tumors, namely, those of ovary, liver, and lung.

The disclosed NOV4 nucloic acid of the invention encoding a Prohibitin -like prolein includes the nucleic acid whose sequence is provided in Table 4A or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 4A while still encoding a protein that maintains its Prohibitin -like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 10% percent of the bases may be so changed.

5

S

2

The disclosed NOV4 protein of the invention includes the Prohibitin -like protein whose sequence is provided in Table 4B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 4B while still encoding a protein that maintains its Prohibitin -like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 43% percent of the residues may be so changed.

8

S

The protein similarity information, expression pattern, and map location for the Prohibitin-like protein and nucleic acid (NOV4) disclosed herein suggest that this NOV4 protein may have important structural and/or physiological functions characteristic of the Prohibitin family. Therefore, the NOV4 nucleic acids and proteins of the invention are useful in potential diagnostic and therapeutic applications. These include serving as a specific or selective nucleic acid or protein diagnostic and/or prognostic marker, wherein the presence or amount of the nucleic acid or the protein are to be assessed, as well as potential therapeutic applications such as the following: (i) a protein therapeutic, (ii) a small molecule drug target, (iii) an antibody target (therapeutic, diagnostic, drug targeting/cytoloxio antibody), (iv) a nucleic acid useful in gene therapy (gene delivery/gene ablation), and (v) a composition promoting tissue regeneration in vitro and in vivo.

ä

WO 02/33087 PCT/US01/32496

The NOV4 nucleic acids and proteins of the invention are useful in potential diagnostic and therapeutic applications implicated in various diseases and disorders described below. For example, the compositions of the present invention will have efficacy for treatment of patients suffering from breast cancer (In a sporadic breast cancer, Sato et al. (1992) found a missense mutation from valine (GTC) to alanine (GCC) at codon 88 of the PHB gene), and/or other pathologies. The NOV4 nucleic acids, or fragments thereof, may further be useful in diagnostic applications, wherein the presence or amount of the nucleic acid or the protein are to be assessed.

NOV4 nucleic acids and polypeptides are further useful in the generation of antibodies 10 that bind immunospecifically to the novel substances of the invention for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. For example, the disclosed NOV4 protein has multiple hydrophilic regions, each of which can be used as an immunogen. In one embodiment, a contemplated NOV4 epitope is from about amino acids 40 to 45. In another embodiment, a NOV4 epitope is from about amino acids 60 to 75. In additional embodiments, NOV4 epitopes are from about amino acids 100 to 130, from about amino acids 140 to 160, from about amino acids 180 to 220, and from about amino acids 240 to 260. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

### NOV5

A disclosed NOV5 nucleic acid of 2011 nucleotides (also referred to as djt 182a14\_da1) encoding a novel Macrophage Stimulating Protein Precursor -like protein is shown in Table 5A. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 1-3 and ending with a TAG codon at nucleotides 1999-2001. A putative untranslated region downstream from the termination codon is underlined in Table 5A, and the start and stop codons are in bold letters.

Table 5A. NOV5 Nucleotide Sequence (SEQ ID NO:15)

ස

The NOV5 nucleic acid was identified on the q21 region of chromosome 3 and has 1508 of 1524 bases (98%) identical to a gb:GENBANK-ID:HUMMST1A acc:L11924 mRNA from Homo sapiens (Homo sapiens macrophage-stimulating protein (MST1) mRNA, complete cds (E = 0.0).

S

A disclosed NOV5 polypeptide (SEQ ID NO:16) encoded by SEQ ID NO:15 is 666 annino acid residues and is presented using the one-letter code in Table 5B. Signal P, Psort and/or Hydropathy results predict that NOV5 has a signal peptide and is likely to be localized in the lysosome (lumen) with a certainty of 0.5493. In other embodiments, NOV5 may also be localized to extracellularly with acertainty of 0.3700, the microbody (peroxisome) with a certainty of 0.1588, or the endoplasmic reticulum (membrane) with a certainty of 0.1000. The most likely cleavage site for a NOV5 peptide is between amino acids 18 and 19, at: VPG-QR.

quilfitamlofamb00024, PAN, PAN domain. The PAN domain contains a conserved core of three disulphide bridges. In some members of the family there is an additional fourth disulphide bridge the links the N and C terminh of the domain. The domain is found in diverse protein, in some they mediate protein-grotein interactions, in others they mediate protein-grotein interactions. (SEQ ID NO.159) Score ~ 50.1 bits (118), Expect = 4e-07

Macrophage-stimulating protein (MSP) is an 80-kD serum protein with homology to hepatocyte growth factor (HGE)(Sakamoto O, et.al.; J Clin Invest 1997 Feb 15;99(4):701-9). Its receptor, RON tyrosine kinase, is a new member of the HGF receptor family. The MSP-RON signaling pathway has been implicated in the functional regulation of mononuclear phagocytes. However, the function of this pathway in other types of cells has not been elucidated. Here we show that in contrast to the HGF receptor, which was expressed at the busolateral surface, RON was localized at the apical surface of ciliated epithelia in the airways and oviduct. In addition, MSP was found in the bronchoalveolar space at biologically significant concentrations. MSP bound to RON on normal human bronchial epithelial cells with a high affinity (Kd = 0.5 nM) and induced autophosphorylation of RON. Activation of RON by MSP led to a significant increase in ciliary beat frequency of human nasal cilia. These findings indicate that the ciliated epithelium of the nucocciliary transport apparatus is a novel target of MSP. Ciliary motility is critical for mucocciliary transport. Our findings suggest that the MSP-RON signaling pathway is a novel regulatory system of mucociliary function and might be involved in the host defense and fertilization.

~

2

2

Macrophage stimulating protein (MSP; 142408), also known as hepatocyte growth factor-like protein (HGFL), is structurally related to hepatocyte growth factor. Gaudino et al. (EMBO J. 13: 3524-3532, 1994) showed that the RON gene is expressed at the cell surface of several epithelial cell types in addition to granulocytes and monocytes. The RON mRNA is translated into a glycosylated precursor that is cleaved into a 185-kD heterodimer of 35-kD (alpha) and 150-kD (beta) subunits joined by the predicted disulfide linkage. Gaudino et al. (1994) further demonstrated that the beta chain undergoes tyrosine phosphorylation upon stimulation by MSP. By isotopic in situ hybridization, Ronsin et al. (Oncogene 8: 1195-1202, 1993) mapped the RON gene to 3p21, with the most probable location being 3p21.3. The gene

23

WO 02/33087 PCT/US01/32496

encoding MSP is also located on 3p21, a region of frequent deletion or mutation in small cell lung and renal carcinoma.

The genes encoding hepatocyte growth factor (HGF; 142409) and its MET receptor are located on 7q. The location of ligand and receptor on the same chromosome, and the structural similarities between MSP and HGF suggested that the ligand for RON might be MSP. Wang et al. (Science 266: 117-119, 1994) showed that this is indeed the case. Their experiments established that the RON gene product is a specific cell surface receptor for MSP. A human hepatoma (HepG2) cell line library was screened with an oligonucleotide probe for macrophage stimulating protein (MSP) to clone an MSP cDNA(Xoshimura T, et al.; J Biol

10 Chem 1993 Jul 25;268(21):15461-8). Deduced sequences of isolated clones were compared with peptide fragment sequences of MSP. MSP9 cDNA encoded most of the known sequence of MSP except for a small segment of fite 5' end of the open reading frame. Consequently, a hybrid 2300-base pair cDNA that encoded the complete MSP amino acid sequence was constructed from 2 clones. Culture fluid from COS-7 cells transfected with this full-length MSP cDNA had MSP biological activity, and the expressed MSP was detected by

immunoprecipitation with antibody against native MSP. The deduced arnino acid sequence of immunoprecipitation with antibody against native MSP. The deduced arnino acid sequence of MSP includes 4 kringle domains, which have been found in hepatocyte growth factor and several proteins of the blood coagulation system. Among them, MSP has the highest sequence similarity to hepatocyte growth factor (45% identity). The MSP cDNA hybridized strongly to mRNA from liver, and to a lesser extent to mRNA from kidney and pancreas, suggesting that a cell type in the liver is the source of MSP. Several cloned and sequenced MSP cDNAs had insertions or deletions, suggesting that alternatively spliced MSP mRNAs may occur. This was reflected in Northern blots probed with an MSP cDNA, which showed more than one mRNA species. Furthermore, although the gene coding for MSP is on chromosome 3, the sequence of one of the cDNAs was identical with a unique sequence in chromosome 1, indicating that

Although the hepatocyte growth factor-like protein (HLP) shares a 50% homology with the hepatocyte growth factor, the biological function of HLP has remained unknown (Shimamoto A, et.al.; FEBS Lett 1993 Oct 25;333(1-2):61-6). Addition of conditioned medium of COS-7 cells transfected with the expression plasmid for HLP cDNA to cultures of resident peritoneal macrophages induced specific activation of macrophages, and the factor which stimulates macrophages was purified from the conditioned medium. The purified prolein showed M(r) of 85 kDa on SDS-PAGE, and this M(r) is in agreement with that of macrophage-stimulating protein (MSP) previously purified from human serum, as well as with

8

there may be a family of MSP genes, located on chromosomes 3 and 1.

7

WO 02/33/087

PCT/US01/32496

the predicted M(r) of HLP. Amino acid composition of the purified protein coincided with the compositions of human HLP and MSP. Together with the finding that the partial amino acid sequences of MSP are highly homologous to that of HLP, we conclude that the biological function of HLP is to activate macrophages and that HLP and MSP are identical molecules.

'n

The disclosed NOV5 nucleic acid of the invention encoding a Macrophage Stimulating Protein Precursor -like protein includes the nucleic acid whose sequence is provided in Table SA or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table SA white still encoding a protein that maintains its Macrophage Stimulating Protein Precursor -like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 10% percent of the bases may be so changed.

5

⇆

The disclosed NOV5 protein of the invention includes the Macrophage Stimulating Protein Precursor -like protein whose sequence is provided in Table 5B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 5B while still encoding a protein that maintains its Macrophage Stimulating Protein Precursor -like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 39% percent of the residues may be so changed.

25

20

The NOV5 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in Aicardi-Goutieres syndrome 1; Brugada syndrome; Deafness, autosomal recessive 6; Heart block, nonprogressive; Heart block, progressive, 2; lehthyosiforme erythrodenna, congenital, nonbullous; Long QT syndrome-3; Night blindness; congenital stationary; Pituitary ACTH-secreting adenoma; Small-cell cancer of lung; Ventricular fibrillation, idiopathic; entricular tachycardia, idiopathic; HIV infection, susceptibility/resistance to; Von Hippel-Lindau (VHL) syndrome; Cirrhosis; Transplantation

ಜ

WO 02/33087 PCT/US01/32496

as well as other diseases, disorders and conditions. The NOV5 nucleic acid, or fragments thereof, may further be useful in diagnostic applications, wherein the presence or amount of the nucleic acid or the protein are to be assessed.

2 5 S that bind immunospecifically to the novel substances of the invention for use in therapeutic or epitope is from about amino acids 20 to 80. In other embodiments, NOV5 epitope is from art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodics" functional analysis of various human disorders, which will help in understanding of pathology to 340, from about amino acids 350 to 460, from about amino acids 500 to 530, from about each of which can be used as an immunogen. In one embodiment, contemplated NOV5 section below. For example the disclosed NOVS protein have multiple hydrophilic regions diagnostic methods. These antibodies may be generated according to methods known in the of the disease and development of new drug targets for various disorders. 420 to 460. This novel protein also has value in development of powerful assay system for amino acids 570 to 590, and from about amino acids 600 to 620, or from about amino acids about amino acids 90 to 120, from about amino acids 140 to 180, from about amino acids 190 NOV5 nucleic acids and polypeptides are further useful in the generation of antibodies

NOV6

3

A disclosed NOV6 nucleic acid of 634 nucleotides (also referred to as GM382a20\_A) encoding a novel Fatty Acid-Binding Protein-like protein is shown in Table 6A. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 58-60 and ending with a TAA codon at nucleotides 460-462. A putative untranslated region upstream from the initiation codon and downstream from the termination codon is underlined in Table 6A, and the start and stop codons are in bold letters.

Table 6A. NOV6 Nucleotide Sequence (SEQ ID NO:17)

25

WO 02/33087 PCT/USU1/32496

The disclosed NOV6 nucleic acid sequence, located on chromosome 15, has 537 of 589 bases (91 %) identical to a Fatty Acid-Binding Protein mRNA from *Houro sapiens* (GENBANK-ID: HUMFABPHA) (E = 3.7e<sup>-102</sup>).

A disclosed NOV6 polypeptide (SEQ ID NO:18) encoded by SEQ ID NO:17 is 134 amino acid residues and is presented using the one-letter amino acid code in Table 6B. Signal P, Psort and/or Hydropathy results predict that NOV6 contains no signal peptide and is likely to be localized in the cytoplasm with a certainty of 0.4500. In other embodiments, NOV6 is also likely to be localized to the mitochondrial matrix space with a certainty of 0.3600, or to the lysosome (lumen) with a certainty of 0.1000.

Fatty acid metabolism in mammalian cells depends on a flux of fatty acids, between the plasma membrane and mitochondria or peroxisomes for beta-oxidation, and between othe cellular organelles for lipid synthesis. The fatty acid-binding protein (FABP) family consists of small, cytosolic proteins believed to be involved in the uptake, transport, and solubilization of their hydrophobic ligands. Members of this family have highly conserved sequences and tertiary structures. Fatty acid-binding proteins were first isolated in the intestine (FABP2; OMIM- 134640) and later found in liver (FABP1; OMIM- 134650), striated muscle (FABP3; OMIM- 134651), adipocytes (FABP4; OMIM- 600434) and epidermal tissues (E-FABP; CDB ID:136450).

င္သ

7

å

WO 02/33087 PCT/US01/32496

Epidermal fatty acid binding protein (E.FABP) was cloned by as a novel keratinocyte protein by Madsen et al (1992, PMID: 1512466) from skin of psoriasis patients. Later using quantitative Western blot analysis, Kingma et al. (1998, PMID: 9521644) have shown that in addition to the skin, bovine E-FABP is expressed in relina, testis, and lens. Since E-FABP was originally identified from the skin of psoriasis patients, it is also known as psoriasis-associated fatty acid-binding protein (PA-FABP). PA-FABP is a cytoplasmic protein, and is expressed in keratinocytes. It is highly up-regulated in psoriatio skin. It shares similarity to other members of the fatty acid-binding proteins and belongs to the fatpi/p2/crbp/crabp family of transporter. PA-FABP is believed to have a high specificity for fatty acids, with highest the affinity. PA-FABP may be involved in keratinocyte differentiation.

Immunohistochemical localization of the expression of E-FABP in psoriasis, basal and squamous cell carcinomas has been carried out in order to obtain indirect information, at the cellular level, on the transport of the fatty acidss. (Masouye et al, 1996, PMID: 8726632). E-FABP was localized in the upper stratum spinosum and stratum granulosum in normal and non-lesional psoriatic skin. In contrast, lesional psoriatic epidermis strongly expressed E-FABP in all suprabasal layers, like nonkeratinized oral mucosa. The basal layer did not express E-FABP negative whereas only well-differentiated cells of squamous cell carcinomas were E-FABP negative whereas only well-differentiated cells of squamous cell carcinomas were keratinocyte differentiation and that the putative role of E-FABP should not be restricted to the formation of the skin lipid barrier. Since the pattern of E-FABP expression mimics cellular FA transport, our results suggest that lesional psoriatic skin and oral mucosa have a higher metabolism/transport for FAs than normal and non-lesional psoriatic epidermis.

The disclosed NOV6 nucleic acid of the invention encoding a Fatty acid binding protein-like protein includes the nucleic acid whose sequence is provided in Table 6A or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 6A while still encoding a protein that maintains its Fatty acid binding protein-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example,

ಜ

WO 02/33087 PCT/US01/32496

modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivalized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antiscnse binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 10% percent of the bases may be so changed.

S

The disclosed NOV6 protein of the invention includes the Fatty acid binding protein-like protein whose sequence is provided in Table 6B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 6B while still encoding a protein that maintains its Fatty acid binding protein-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 14% percent of the residues may be so changed.

2

The above defined information for this invention suggests that these Falty acid binding protein-like proteins (NOV6) may function as a member of a "Fatty acid binding protein-like proteins (NOV6) may function as a member of a "Fatty acid binding in proteinfamily". Therefore, the NOV6 nucleio acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various palhologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration in vivo and in vitro of all tissues and cell types composing (but not limited to) those defined here.

2

The nucleic acids and proteins of NOV6 are useful in Cardiomyopalhy, Atherosclerosis, Hypertension, Congenital heart defects, Aortic stenosis, Atrial septal defect (ASD), Atrioventricular (A-V) canal defect, Ductus arteriosus, Pulmonary stenosis, Subaortic stenosis, Ventricular aceptal defect (VSD), valve diseases, Tuberous sclerosis, Scleroderma, Transplantation, Endometriosis, Inflammatory bowel disease, Diverticular disease, Hirschsprung's disease, Crobn's Disease, Hemophilia, hypercoagulation, Idiopathic thrombocytopenic purpura, immunodeficiencies, Osteoporosis, Hypercalceimia, Arthritis, Von Hippel-Lindau (VHL) syndrome, Alzheimer's disease, Stroke, Tuberous sclerosis, hypercalceimia, Parkinson's disease, Huntington's disease, Cerebral palsy, Epilepsy, Asthma, allergy, ARDS, Lesch-Nyhan syndrome, Multiple sclerosis, Leukodystrophies, Behavioral disorders, Addiction, Anxiely, Pain, Neuroprotection Fertility, psoriasis, cancer including but not limited to basal and squamous cell carcinomas, obesity, diabetis, and/or other pathologies and disorders involving falty acid transport of skin, oral nuccosa as well as other organs. The novel NOV6 nucleic acid encoding NOV6 protein,, or fragments thereof, may further be

2

30

WO 02/33087

PCT/US01/32496

useful in diagnostic applications, wherein the presence or amount of the nucleic acid or the protein are to be assessed. These materials are further useful in the generation of antibodies that bind immunospecifically to the novel substances of the invention for use in therapeutic or diagnostic methods.

NOV6 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immunospecifically to the novel substances of the invention for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. For example the disclosed NOV6 protein have multiple hydrophilic regions, each of which can be used as an immunogen. In one embodiment, contemplated NOV6 epitope is from about amino acids 10 to 35. In other embodiments, NOV6 epitope is from about amino acids 10 to 35. In other embodiments on the acids 90 to 110. This novel protein also has value in development of powerful assay system for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

#### NOV7

A disclosed NOV7 nucleic acid of 822 nucleotides (also referred to sygo\_draft\_dj895c5\_20000819) encoding a novel Gap junction beta-5 protein-like protein is shown in Table 7A. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 1-3 and ending with a TAA codon at nucleotides 800-802. In Table 7A, the 5' and 3' untranslated regions are underlined and the start and stop codons are in bold

Table 7F. Domain Analysis of NOV7
gn. | Smart | Smart

Gap junctions are conduits that allow the direct cell-to-cell passage of small cytoplasmic molecules, including ions, metabolic intermediates, and second messengers, and thereby mediate intercellular metabolic and electrical communication. Gap junction channels thereby mediate intercellular metabolic and electrical communication. Gap junction channels consist of connexin protein subunits, which are encoded by a multigene family. Richard et al. (Nature Genet. 20: 366-369, 1998) identified 2 expressed sequence tags (ESTs) from the human EST database by their similarity to mouse Gjb3 (see 603324) and Gjb5. By radiation hybrid mapping, they placed them in proximity to a sequence tagged site (STS) that is linked to GJA4 (121012) at 1p35.1. Richard et al. (1998) determined the cDNA sequences of the genes from which both ESTs were derived. Sequence similarity to rodent connexin genes

genes from which both ESTs were derived. Sequence similarity to rodent connexin genes established them as human homologs of Gjb3 and Gjb5, encoding Cx32 and Cx31.1, respectively. Richard et al. (1998) excluded GJB5 as a candidate gene for erythrokeralodermia variabilis (133200) by sequence analysis. Gap junctions are intercellular channels which connect adjacent cells and allow direct exchange of molecules of low molecular weight between them (Alves LA et al.; Braz J Med Biol Res 2000 Apr;33(4):457-65). Such a communication has been described as fundamental in many systems due to its importance in coordination, proliferation and differentiation. Recently, it has been shown that gap junctional intercellular communication (GJIC) can be modulated by several extracellular soluble factors such as classical hormones, neurotransmitters, interleukins, growth factors and some paracrine

ន

substances. Herein, we discuss some aspects of the general modulation of GJIC by extracellular messenger molecules and more particularly the regulation of such communication in the thymus gland. Additionally, we discuss recent data concerning the study of different neuropeptides and hormones in the modulation of GJIC in thymic epithelial cells. We also suggest that the thymus may be viewed as a model to study the modulation of gap junction communication by different extracellular messengers involved in non-classical circuits, since this organ is under bidirectional neuroimmunoendocrine control. The

2

their biological functions in skin. The importance of gap junctional intercellular assembly, and properties of the components of the complex and diverse connexin system, and (Richard G; Exp Dermatol 2000 Apr;9(2):77-96). This review summarizes the structure, homeostasis, growth control, development, and synchronized response of cells to stimuli intercellular signaling system mediated by connexin channels is crucial for maintaining tissue

S dominant inherited disorders are caused by germline mutations in the connexin genes GJB3 variabilis and palmoplantar keratoderma associated with hearing loss. These autosomal hearing function of the inner ear is illustrated by the examples of erythrokeratodermia communication for normal development and differentiation of human epidermis as well as the

2 5 junction channels are sites of cytoplasmic communication between contacting cells. In communication, resulting in phenotypic manifestation in patients with these disorders. Gap effect on normal connexin channel function and perturb gap junctional intercellular studies of individual connexin mutations suggest that they may exert a dominant inhibitory (encoding connexin-31) and GJB2 (encoding connexin-26), respectively. Recent functional

could be defined by the relative importance of permeant substances, resulting in coordination pathways under specific physiological conditions. Functional roles of gap junction channels suggest that channels composed of different Cxs are regulated differentially by intracellular define which ions and small molecules penneale them. Differences in Cx primary sequences Cx composition, gap junction channels show different gating and permeability properties tha gene family (Sacz JC ct.al.; Braz J Med Biol Res 2000 Apr;33(4):447-55). According to their vertebrates, they consist of protein subunits denoted connexins (Cxs) which are encoded by systems establish transient homo- and heterocellular contacts at various steps of the immune of electrical and/or metabolic cellular responses. Cells of the native and specific immune

20

ಜ 25 junctions or "gap junction-like" structures. Partial characterization of the molecular control them have been published recently. Studies designed to elucidate their physiological roles suggest that they might permit coordination of cellular events which favor the effective composition of some of these plasma membrane structures and regulatory mechanisms that revealed that many intercellular contacts between cells in the immune response present gap response. Morphological and functional studies reported during the last three decades have

and timely response of the immune system. Antitumor suicide gene therapy is one of the prodrug into a cytotoxic drug. Because this therapeutic gene cannot be easily introduced into emerging strategies against cancer (Mesnil M et. al.; Cancer Res 2000 Aug 1;60(15):3989-99) the whole cell population of a tumor, the successful cradication of tumors depends on a . It consists of the introduction into cancer cells of a gene capable of converting a nontoxic

> ganciclovir, has been extensively and successfully used in some animal models exhibiting a the thymidine kinase gene from the herpes simplex virus, in combination with the prodrug this phenomenon through various means to achieve tumor eradication. One such suicide gene, in which it is not itself present. From a therapcutic point of view, it may be crucial to enhance phenomenon called the "bystander effect," by which the introduced gene can affect even cells

bystander effect both in vitro and in vivo, here we review possible molecular strategies for cells to surrounding cells that do not express it. Because GJIC appears to be a mediator of the of ganciclovir, which pass directly from herpes simplex virus thymidine kinase-expressing strong bystander effect. Among the mechanisms involved in this phenomenon, gap junctional intercellular communication (GJIC) is directly involved in the transfer of the toxic metabolites

5

Synapses are classically defined as close connections between two nerve cells or between a enhancing the extent of tumor cell death by increasing the intratumoral GIIC capacity. neuronal cell and a muscle or gland cell across which a chemical signal (i.e., a neurotransmitter) and/or an electrical signal (i.e., current-carrying ions) can pass (Rozental R

20 2 vertebrate neurons. As is evidenced by the range of topics covered in this issue, research ct.al.; Brain Res Brain Res Rev 2000 Apr;32(1):11-5). The definition of synapse was and that expression patterns coincide with tissue compartmentalization and function and that major findings being that specific cell types in the brain expresses specific types of connexins dealing with gap junctions in the nervous system has expanded enormously in the past decade definition of synapses is discussed further in the chapter by Mike Bennett. who provided the developed by Charles Sherrington and by Ramon y Cajal at the beginning of this century and first functional demonstration of electrical transmission via gap junction channels between refined by John Eccles and Bernard Katz 50 years later; in this collection of papers, the

ઝ of the remodeling data gave rise to slow conduction on the order of a few centimeters per a simple model of human ventricular myocardium, we found that quantitative remodeling data cell borders in a variety of cardiac diseases (Jongsma HJ et.al.; Circ Res 2000 Jun gap junction channels, are reduced in number or redistributed from intercalated disks to lateral resistivity (and thus cellular geometry) is much more important than commonly realized. None velocity and the anisotropy ratio. Especially for longitudinal conduction, cytoplasmic extracted from the literature gave rise to only small to moderate changes in conduction 23;86(12):1193-7). This "gap junction remodeling" is considered to be arrhythmogenic. Using

25

thesecompartments change during development. Connexins, the protein molecules forming

bone turnover (Donahue HJ; Bone 2000 May; 26(5):417-22). Indeed, the structural success of second. Physical signals, in particular mechanical loading, are clearly important regulators of

the skeleton is due in large part to the bone's capacity to recognize some aspect of its functional environment as a stimulus for achievement and retention of a structurally adequate morphology. However, while the skeleton's ability to respond to its mechanical environment is widely accepted, identification of a reasonable mechanism through which a mechanical "load" could be transformed to a signal relevant to the bone cell population has been elusive. In addition, the downstream response of bone cells to load-induced signals is unclear. In this work, we review evidence suggesting that gap junctional intercellular communication (GJIC) contributes to mechanotransduction in bone and, in so doing, contributes to the regulation of bone cell differentiation by biophysical signals. In this context, mechanotransduction is defined as transduction of a load-induced biophysical signal, such as fluid flow, substrate deformation, or electrokinetic effects, to a cell and ultimately throughout a cellular network. Thus, mechanotransduction would include interactions of extracellular signals with cellular membranes, generation of intracellular second messengers, and the propagation of these messengers, or signals they induce, through a cellular network. We propose that gap junctions contribute largely to the propagation of intracellular signals.

The disclosed NOV7 nucleic acid of the invention encoding a Gap Junction Beta-5 Protein-like protein includes the nucleic acid whose sequence is provided in Table 7A or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 7A while still encoding a protein that maintains its Gap Junction Beta-5 Protein-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 16% percent of the bases may be so changed.

25

The disclosed NOV7 protein of the invention includes the Cap Junction Beta-5 Protein-like protein whose sequence is provided in Table 7B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 7B while still encoding a protein that maintains its Cap Junction Beta-

5 Protein-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 33% percent of the residues may be so changed.

The protein similarity information, expression pattern, and map location for the Gap Junction Beta-5 Protein-like protein and nucleic acid (NOV7) disclosed herein suggest that NOV7 may have important structural and/or physiological functions characteristic of the Gap Junction Beta-5 Protein-like family. Therefore, the NOV7 nucleic acids and proteins of the invention are useful in potential diagnostic and therapeutic applications. These include serving as a specific or selective nucleic acid or protein diagnostic and/or prognostic marker, wherein the presence or amount of the nucleic acid or the protein are to be assessed, as well us polential therapeutic applications such as the following: (i) a protein therapeutic, (ii) a small molecule drug target, (iii) an antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), (iv) a nucleic acid useful in gene therapy (gene delivery/gene ablation), and (v) a composition promoting tissue regeneration in vitro and in vivo.

The NOV7 nucleic acids and proteins of the invention are useful in potential diagnostic and therapeutic applications implicated in various diseases and disorders described below and/or other pathologies. For example, the compositions of the present invention will have efficacy for treatment of patients suffering from Deafness, autosomal dominant 2; Elliptocytosis-1; Fucosidosis; Hypophosphatasia (adult, childhood, infantile); Muscle-eyebrain disease; Neuropathy, paraneoplastic sensory; Porphyria cutanea tarda; Porphyria, hepaloerythropoietic; Schwartz-Jampel syndrome; Thrombocytopenia, congenial amegakaryocytic; Charcot-Mario-Tooth neuropathy-2A; Galactose epimerase deficiency; Glucose transport defect, blood-brain barrier; Kostmann neutropenia; Muscular dystrophy, congenital, with early spine rigidity; Myopathy due to succinate dehydrogenase deficiency;

20

2

Breast cancer, ductal; Comeal dystrophy, crystalline, Schnyder; Hyperprolinemia, type II; Inflammatory bowel disease 7; Malignant melanoma, cutaneous; Neuroblastoma; Prostate cancer-brain cancer susceptibility; erythrokeratodermia variabilis; palmoplantar keratoderma; diseases and disorders involving intercellular metabolic and electrical communication; diseases and disorders involving coordination, proliferation and differentiation; diseases and

SCID due to LCK deficiency; Colorectal cancer, resistance to; Bartter syndrome, type 3;

disorders involving maintainance of lissue homcostusis, growth control, development, and synchronized response of cells to stimuli; diseases and disorders involving the the immune system; diseases and disorders involving regulation of bone cell differentiation, and/or other pathologies/disorders. The NOV7 nucleic acid, or fragments thereof, may further be useful in

diagnostic applications, wherein the presence or amount of the nucleic acid or the protein are

functional analysis of various human disorders, which will help in understanding of pathology 220 to 255. This novel protein also has value in development of powerful assay system for about amino acids 90 to 140, from about amino acids 170 to 180, or from about amino acids epitope is from about amino acids 40 to 70. In other embodiments, NOV7 epitope is from each of which can be used as an imminogen. In one embodiment, contemplated NOV7 section below. For example the disclosed NOV7 protein have multiple hydrophilic regions, art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" diagnostic methods. These antibodies may be generated according to methods known in the of the disease and development of new drug targets for various disorders that bind immunospecifically to the novel substances of the invention for use in therapeutic or NOV7 nucleic acids and polypeptides are further useful in the generation of antibodies

coordinate heavy metal atoms such as zinc, cadmium, and copper via mercaptide linkages. In brain, and MT-IV is only expressed in certain stratified squamous epithelia. which are expressed in most organs, MT-III (139255) expression appears to be restricted to the groups designated MT-1 and MT-II. Masters et al. (1994) noted that, unlike MT-I and MT-II. hormones. In man, metallothioneins are encoded by at least 10 to 12 genes separated into 2 synthesis is induced by either ionized zinc or ionized cadmium and by glucocorticoid human liver, MTs occur in 2 major fonns, MT-I and MT-II (156360). In HeLa cells, MT (MTs) as a family of low molecular weight, heavy metal-binding proteins characterized by a in prokaryotes. In mammals, the cysteine residues are absolutely conserved and serve to per molecule of protein. They are ubiquitous in the animal and plant kingdoms and are found high cysteine content and lack of aromatic amino acids. MTs bind 7 to 12 heavy metal atoms Masters et al. (Proc. Nat. Acad. Sci. 91: 584-588, 1994) described metallothioneins

2

copper loxicity in the Menkes disease (309400) and murine 'Mottled' phenotypes (X-linked metalloproteins; and to protect against reactive oxygen species. MTs may also protect against diseases resulting in copper deficiency) as well as in Wilson disease (277900); see also the homeostasis during development; to regulate synthesis, assembly, or activity of zinc MTs have been postulated to detoxify metals; to play a role in zinc and copper

ylucocorticoids

#### MAPPING

Karin et al. (Proc. Nat. Acad. Sci. 81: 5494-5498, 1984) used several different hybridization probes derived from cloned and functional human MT1 and MT2 genes to map the genes in somatic cell hybridization studies. They concluded that most of the human genes are clustered on chromosome 16. Analysis of RNA from somatic cell hybrids indicated that all hybrids that contain human chromosome 16 express both MT1 and MT2 mRNA and that expression is regulated by both heavy metal ions and glucocorticoid hormones.

S

In the mouse, the metallothionein genes are on chromosome 8, which has other homology to human chromosome 16; by somatic cell hybridization, Cox and Palmiter (Hum. Genet. 64: 61-64, 1983) assigned the MT-1 structural gene to mouse chromosome 8, which also carries glutathione reductase in the mouse. (By chance the human 8 also carries glutathione reductase.)

2

Schmidt et al. (Science 224: 1104-1106, 1984) concluded that MT1 is located between PGP (172280) and DLA4 (125860) and is probably on the long arm 16cen-16q21 because APRT (102600), a 16q marker, and MT1 are both on mouse chromosome 8, whereas HB alpha (141800), a 16p marker, is on mouse chromosome 11. They stated that analysis of the involvement of the MT genes in Wilson disease (277900) and in acrodermatitis enteropathica (201100) would be of great interest.

2

20

By gel transfer hybridization analysis of the DNA from human-rodent cell hybrids, Schmidt et al. (J. Biol. Chem. 260: 7731-7737, 1985) showed that chromosome 16 contains a cluster of metallothionein sequences, including 2 functional metallothionein I genes (156351 and 156352) and a functional metallothionein II gene. The remaining sequences, including a processed pseudogene, are dispersed to at least 4 other autosomes. The absence of metallothionein sequences from the X chromosome indicates that the Menkes disease mutation affects metallothionein expression by a 'trans-acting' mechanism. The processed pseudogene is on chromosome 4 and shows allelic variation (Karin and Richards, Nucleic Acids Res. 10: 3165-3173, 1982). Two MT genes are on chromosome 1 but not close together: one is on the distal two-thirds of the short arm and the second probably on the long arm. One metallothionein gene is on chromosome 20 and another is on chromosome 18.

25

By in situ hybridization, Le Beau et al. (Nature 313: 709-711, 1985) assigned the metallothionein gene cluster to 16q22. This band is a breakpoint in 2 specific rearrangements, inv(16)(p13q22) and t(16;16)(p13;q22), found in a subgroup of patients with acute myelomonocytic leukemia. Hybridization of an MT probe to malignant cells from patients

8

ಜ

WO 02/33087

PCT/US01/32496

with one or the other of these rearrangements showed that the breakpoint at 16q22 splits the MT gene cluster. The findings were interpreted as indicating that the MT genes or their regulatory regions may function as an activating sequence for an as yet unidentified cellular gene located at 16p13. Band 16p22 carries 2 fragile sites: the rare FRA16B and the common polytic curves at 16p13. Band 16p22 carries 2 fragile sites: the rare FRA16B and the common polytic curves at 16p13.

FRA IGC. Simmers et al. (Science 236: 92-94, 1987) showed that the specific leukemic break that is situated in the metallothionein gene cluster lies proximal to both fragite sites; therefore, neither of these fragile sites could have played a role in the breakage.

Using high-resolution in situ hybridization, Sutherland et al. (Cylogenet. Cell Genet. 51: 1087, 1989, Genomics 6: 144-148, 1990) corrected the mapping of the human metallothionein gene complex to 16q13. They found, furthermore, that the complex is not disrupted by the rearrangement breakpoint on 16q in the patients with myelomonocytic leukemia with abnormal eosinophils, as had previously been reported. They showed that the order is con-MT-FRA16B-D16S4--inversion breakpoint--HB--qter.

2

Foster et al. (J. Biol. Chem. 263: 11528-11535, 1988) indicated that 4 functional MT1 genes had been identified and mapped to 16q: MT1A, MT1B (156349), MT1E (156351), and MT1F (156352). They also characterized a fifth MT gene, MT1G (156353). West et al. (Genomics 8: 513-518, 1990) mapped the cluster of MT genes in an 82.1-kb region of 16q13. Of the 14 tightly linked genes, 6 had not previously been described. The mapped genes included the single MT2 gene, MT2A, and at least 2 pseudogenes, MT1C and MT1D. The genes were flanked by the single MT2A gene at one end and a gene labeled MT1X (156359) at the other. The order of genes, beginning at the MT2A end, was 1L--1E-1K--1J--1A--1D-1C--1B--1F--1G--1H--1. This was also the 5-prime to 3-prime direction of transcription for all the genes except MT1G, which had a tail-to-tail, head-to-head orientation to MT1F and MT1H, respectively.

#### ANTWAL MODEL

25

To test the proposed detoxification and homeostasis functions of mammalian MTs in vivo, Masters et al. (1994) inactivated both alleles of the Mt1 and Mt2 genes in embryonic stem cells and generated mice homozygous for these mutant alleles. These mice were viable and reproduced normally when reared under normal laboratory conditions. They were, however, more susceptible to hepatic poisoning by cadmium. This suggested to Masters et al. (1994) that these widely expressed MTs are not essential for development but do protect against cadmium toxicity.

WO 02/33087

Human Menkes disease (309400) and the murine 'Mottled' phonotype are X-linked diseases that result from copper deficiency due to mutations in ATP7A, a copper-effluxing ATPase (300011). Male mice with the Mottled-Brindled allele accumulate copper in the intestine, fail to export copper to peripheral organs, and die a few weeks after birth. Much of the intestinal copper is bound by metallothionein. To determine the function of MT in the presence of Alp7a deficiency, Kelly and Palmiter (Nature Genet. 13: 219-222, 1996) crossed Mottled-Brindled females with males that bear a targeted disruption of the Mt1 and Mt2 genes. On the metallothionein-deficient background most Mottled males as well as heterozygous Mottled females died before embryonio day 11. The authors explained the lethality in females by preferential inactivation of the paternal X chromosome in extra embryonic tissues and resultant copper toxicity in the absence of MT.

In support of this hypothesis, Kelly and Palmiter (1996) found that cell lines derived from metallothionein deficient, Mottled embryos were very sensitive to copper toxicity. They concluded that MT is essential to protect against copper toxicity in embryonic placenta, providing a second line of defense when copper effluxers are defective. They also stated that MT probably protects against hepatic copper toxicity in Wilson disease and the LEC rat mode in which a similar copper effluxer, ATP7B (277900), is defective, because MT accumulates to high levels in the liver in those diseases.

The disclosed NOV8 nucleic acid of the invention encoding a MT-like protein includes the nucleic acid whose sequence is provided in Table 8A, or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 8A while still encoding a protein that maintains its MT-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar

in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 10% percent of the bases may be so changed.

phosphate backbones are modified or derivatized. These modifications are carried out at least

The disclosed NOV8 protein of the invention includes the MT-like protein whose sequence is provided in Table 8B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 2 while still encoding a protein that maintains its MT-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 61% percent of the residues may be so changed.

20

The invention further encompasses antibodies and antibody fragments, such as  $F_{ab}$  or  $(F_{ab})_2$ , that bind immunospecifically to any of the proteins of the invention.

The above defined information for this invention suggests that this MT-like protein (NOV8) may function as a member of a "MT family". Therefore, the NOV8 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic untibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration in vivo and in vitro of all tissues and cell types composing (but not limited to) those defined here.

The NOV8 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in cancer including but not limited to Inflamation,

the MT-like protein of the invention, or fragments thereof, may further be useful in diagnostic useful when administered to a subject in need thereof. By way of nonlimiting example, the toxicity and other such conditions. The NOV8 nucleic acid encoding MT-like protein, and compositions of the present invention will have efficacy for treatment of patients suffering from Gitelman syndrome, Menkes disease, Wilson's disease, acrodermatitis enteropathica, myelomonocytic leukemia, eosinophil disorders, hepatic disorders such as hepatic copper protein (NOV8) may be useful in gene therapy, and the MT-like protein (NOV8) may be Autoinmune disorders, Aging and Cancer. For example, a cDNA encoding the MT-like applications, wherein the presence or amount of the nucleic acid or the protein are to be

The thyroid hormone receptors (TRs) are hormone-dependent transcription factors tha rogulate expression of a variety of specific target genes. They must specifically interact with a number of proteins as they progress from their initial translation and nuclear translocation to heterodimerization with retinoid X receptors (RXRs), functional interactions with other

WO 02/33087 PCT/US01/32496

transcription factors and the basic transcriptional apparatus, and eventually, degradation. To help elucidate the mechanisms that under lie the transcriptional effects and other potential functions of TRs, Lee et al. (Molec. Endoor. 9: 243-254, 1995) used the yeast interaction trap, a version of the yeast 2-hybrid system, to identify proteins that specifically interact with the ligand-binding domain of rat TR-beta (THRB; 190160). They isolated HeLa cell cDNAs encoding several different TR-interacting proteins (TRIPs), including TRIP10. TRIP10 interacted with rat Thrb only in the presence of thyroid hormone. It also showed a ligand-dependent interaction with RXR-alpha (RXRA; 180245), but did not interact with the

10 homology-3 (SH3) domain and shows sequence similarity to a Xenopus fyn homolog (see 137025) and chicken src (see 190090). Northern blot analysis detected a 2.6-kb TRIP 10 transcript in several tissues, with highest expression in skeletal musele.

glucocorticoid receptor (NR3C1; 138040) under any condition. TRIP10 contains a Src

Using the yeast 2-hybrid system to identify proteins that bind to a constitutively active mutant of CDC42 (116952), Aspenstrom (1997) isolated a human B-cell cDNA encoding CDC42-interacting protein-4 (CIP4), which is identical to TRIP10. The predicted 545-amino acid CIP4 protein contains an N-terminal domain that bears resemblance to the nonkinase domain of the FER (176942) and Fes/Fps family of tyrosine kinases, and a C-terminal SH3 domain, In addition, CIP4 shares sequence similarity with a number of proteins that have roles in regulating the actin cytoskeleton. Aspenstrom (Curr. Biol. 7: 479-487, 1997) demonstrated that CIP4 can bind to activated CDC42 in vitro and in vivo. Overexpression of CIP4 in accumulated at the cell periphery, particularly in areas that exhibited membrane ruffling. Coexpression of activated CDC42 and CIP4 led to clustering of CIP4 to a large number of foci

Aspensitrom (1997) concluded that CP4 is a downstream target of activated GTP-bound CDC42, and is similar in sequence to proteins involved in signaling and cytoskeletal control. The author suggested that CP4 may act as a link between CDC42 signaling and regulation of the actin cytoskeleton.

ಜ

The Wiskott-Aldrich syndrome is an inherited X-linked immunodeficiency characterized by thrombocytopenia, eczema, and a tendency toward lymphoid malignancy (Tian L, et.al.; J Biol Chem 2000 Mar 17;275(11):7854-61). Lymphocytes from affected

PCT/US01/32496 WO 02/33087

mediate the association of WASP with microtubules. This may facilitate transport of WASP to Wiskott-Aldrich syndrome protein (WASP) is a multi-domain protein involved in cytoskeletal WASP in COS-7 cells led to the association of WASP with microtubules. In vitro experiments binding of the Src homology 3 domain of C1P4 to the proline-rich segment of WASP. Cdc42 was not required for this interaction. Co-expression of CIP4 and green fluorescent proteinorganization. In a two-hybrid screen, we identified the protein Cdc42-interacting protein 4 mutation 1398S abrogated binding. Deletion of the Cdc42-binding domain of CIP4 did not affect the colocalization of WASP with microtubules in vivo. We conclude that CP4 can individuals have cytoskeletal abnormalities, and monocytes show impaired motility. The cytoskeletal organization. We found that the WASP-CIP4 interaction is mediated by the (CIP4) as a WASP interactor. CIP4, like WASP, is a Cdc42 effector protein involved in responsible for binding to active Cdc42 was localized to amino acids 383-417, and the showed that CIP4 binds to microtubules via its NH(2) tenninus. The region of CIP4 sites of substrate adhesion in hematopoietic cells. 2

WO 02/33087 PCT/US01/32496

may further be useful in diagnostic applications, wherein the presence or amount of the nucleic acid or the protein are to be assessed.

NOV9 nucleic acids and polypeptides are further useful in the generation of antibodics that bind immuno-specifically to the novel NOV9 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodics" section below. The disclosed NOV9 protein has multiple hydrophilic regions, each of which can be used as an immunogen. In one embodiment, a contemplated NOV9 epitope is from about amino acids 25 to 40. In another embodiment, a NOV9 epitope is from about amino acids 45 to 55. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

WO 02/33087 PCT/US01/32496

20 2 5 S family of more than 10, some of which may be pseudogenes or may be expressed in other DNA with the cloned cDNA as a probe showed that the human trypsinogen genes constitute a peptide and an 8-amino acid activation peptide. Southern blot analysis of human genomic 89% homology and the same number of amino acids (247), including a 15-amino acid signal pair conserved in mouse and man. Emi et al. (1986) isolated cDNA clones for 2 major human enzyme replacement (Townes, 1972). Trypsin (EC 3.4.21.4), like elastase (130120), is a trypsinogen isozymes from a pancreatic cDNA library. The deduced amino acid sequences had chromosome 6 (Honey et al., 1984). Carboxypeptidase A (114850) and trypsin are a syntenic 7qter by study of hybrids with a deletion of this segment. The trypsin gene is on mouse nucleotide sequences of cDNAs representing 2 pancreatic rat trypsinogens. Using a rat cDNA member of the pancreatic family of serine proteases. MacDonald et al. (1982) reported an affected female who also had imperforate anus. The clinical picture in enterokinase l gene sequences cosegregated with chromosome 7, and assigned the gene further to 7q22probe, Honey et al. (1984, 1984) found that a 3.8-kb DNA fragment containing human trypsin produced by the pancreas. Oral pancrealin represents a therapeutically successful form of trypsinogen but in the synthesis of the enterokinase which activates proteolytic enzymes deficiency (226200) is closely similar; however, the defect is not in the synthesis of Townes (1965) had died, apparently of the same condition. Morris and Fisher (1967) reported al. (1967). A protein hydrolysate diet was beneficial. A male sib of the first palient reported by electrolytes were features of 2 affected male infants reported by Townes (1965) and Townes et Failure to thrive, nutritional edema, and hypoproteinemia with normal sweat

Rowen et al. (1996) found that there are 8 trypsinogen genes embedded in the beta T25 cell receptor locus or cluster of genes (TCRB; 186930) mapping to 7q35. In the 685-kb DNA
segment that they sequenced they found 5 tandemly arrayed 10-kb locus-specific repeals
(homology units) at the 3-prime end of the locus. These repeals exhibited 90 to 91% overall
nucleotide similarity, and embedded within each is a trypsinogen gene. Alignment of
pancreatic trypsinogen cDNAs with the germline sequences showed that these trypsinogen
genes contain 5 exons that span approximately 3.6 kb. Further analyses revealed 2 trypsinogen
pseudogenes and 1 relic trypsinogen gene at the 5-prime end of the sequence, all in inverted
transcriptional orientation. They denoted 8 trypsinogen genes T1 through T8 from 5-prime to
3-prime.

Rowen et al. (1996) found that only 2 of 3 pancreatically expressed trypsinogen cDNAs correspond to trypsinogen genes in the TCRB locus; T4 was denoted trypsinogen I

ઝ

and T8 was denoted trypsinogen 2 (601564). The third pancreatic cDNA, identified independently as trypsinogen 3 (Tani et al., 1990) and 4 (Wiegand et al., 1993), is distinct from the third apparently functional trypsinogen gene (T6) in the TCRB locus but related to the other pancreatic trypsinogens. Rowen et al. (1996) stated that the T6 gene is deleted in a common insertion-deletion polymorphism; if it is functional, its function is apparently not essential. Some of the trypsinogen genes are expressed in nonpancreatic tissues where their function is unknown. Rowen et al. (1996) noted that the intercalation of the trypsinogen genes in the TCRB locus is conserved in mouse and chicken, suggesting shared functional or regulatory constraints, as has been postulated for genes in the major histocompatibility complex (such as class I, II, and III genes) that share similar long-term organizational relationships.

Rowen et al. (1996) mapped the gene corresponding to the third pancreatic trypsinogen cDNA by fluorescence in situ hybridization. They used a cosmid clone containing 3 trypsinogen genes. Strong hybridization to chromosome 7 and weaker hybridization to chromosome 9 were observed. They isolated and partially sequenced 4 cosmid clones from the ohromosome 9 region. They found that the region represents a duplication and translocation of a DNA segment from the 3-prime end of the TCRB locus that includes at least 7 V(beta) elements and a functional trypsinogen gene denoted T9. The assignment of the PRSS1 gene to 7q35 is established by the demonstration of its sequence within the sequence of the 'locus' for the T-cell receptor beta-chain (Rowen et al., 1996). Since hereditary pancreatitis (167800) has been mapped rather precisely to 7q35 and since a defect in the trypsinogen gene has been identified in hereditary pancreatitis, the ussignment of the trypsinogen gene can be refined from 7q32-qter to 7q35.

20

25

2

Whilcomb et al. (1996) stated that the high degree of DNA sequence homology (more than 91%) present among this cluster of 5 trypsinogen genes identified by Rowen et al. (1996) demanded that highly specific sequence analysis strategies be developed for mutational screening in families with hereditary panoreatitis. This was necessary to ensure that each sequencing run contained only the 2 alteles corresponding to a single gene, thereby permitting detection of heterozygotes in this autosomal dominant disorder, and not a dozen or more alteles from multiple related trypsitogen-like genes, which would make detection of heterozygotes nearly impossible. In a family with hereditary pancreatitis, Whitcomb et al. (1996) found that affected individuals had a single G-to-A transition mutation in the third exon of cationic trypsinogen (276000.0001). This mutation was predicted to result in an arg105-to-his substitution in the trypsin gene (residue number 117 in the more common ohymotrypsin

8

WO 02/33087

PCT/US01/32496

number system). Subsequently, the same mutation was found in a total of 5 different hereditary pancreatitis kindreds (4 from the U.S. and 1 from Italy) containing a total of 20 affected individuals and 6 obligate carriers. The mutation was found in none of the obligate unaffected members (individuals who married into the family). Subsequent haplotyping revealed that all 4 of the American families displayed the same high risk haplotype over a 4-cM region encompassing 7 STR markers, confirming the likelihood that these kindreds shared a common ancestor, although no link could be found through 8 generations. A fifth family from Italy displayed a unique haplotype indicating that the same mutation had occurred on at least 2 occasions. The G-to-A mutation at codon 117 created a novel enzyme recognition site for AfiLLI which provided a facile means to screen for the mutation. As with the obligate

S

Ferec et al. (1999) studied 14 families with hereditary pancreatitis and found mutations in the PRSSI gene in 8 families. In 4 of these families, the mutation (R.117H; 276000.0001) had been described by Whitcomb et al. (1996). Three mutations were described in 4 other families (276000.0002, 276000.0003, 276000.0005).

2

unaffected members of the pancreatitis kindreds, none of 140 controls possessed the G-to-A

2

2

nutation as assayed by the lack of AfIIII digestion of the amplified exonic DNA.

Sahin-Toth et al. (1999) studied the roles of the 2 most frequent PRSS1 mutations in hereditary panoreatitis, R117H and N211 (276000.0002). They stated that the R117H mutation is believed to cause panoreatitis by eliminating an essential autolytic cleavage site in trypsin, thereby rendering the protease resistant to inactivation through autolysis. Sahin-Toth et al. (1999) demonstrated that the R117H mutation also significantly inhibited autocatalytic trypsinogen breakdown under Ca(2+)-free conditions and stabilized the zymogen form of rat trypsin. Taken together with findings demonstrating that the N21I mutation stabilized rat trypsinogen against

2

autoactivation and consequent autocatalytic degradation, the observations suggested a unifying molecular pathomechanism for hereditary pancreatitis in which zymogen stabilization plays a central role.

25

Sahin-Toth and Toth (2000) demonstrated that the R117H and N21I mutations significantly enhance autoactivation of human cationic trypsinogen in vitro, in a manner that correlates with the severity of clinical symptoms in hereditary pancreatitis. In addition, the R117H mutation inhibited autocatalytic inactivation of trypsin, while the N21I mutation had no such effect. Thus, increased trypsinogen activation in the pancreas is presumably the common initiating step in both forms of hereditary pancreatitis, whereas trypsin stabilization may also contribute to hereditary pancreatitis associated with the R117H mutation.

2

acids, and their complements, up to about 40% percent of the bases may be so changed. binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic stability of the modified nucleic acid, such that they may be used, for example, as antisense derivatized. These modifications are carried out at least in part to enhance the chemical modified bases, and nucleic acids whose sugar phosphale backbones are modified or chemical modifications. Such modifications include, by way of nonlimiting example, nucloic acids or nucleic acid fragments, or complements thereto, whose structures include complementary to any of the nucleic acids just described. The invention additionally includes complementary to those just described, including nucleic acid fragments that are protein that maintains its spinesin-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are be changed from the corresponding base shown in Table 10A and 10D while still encoding a thereof. 15

# NOVX Nucleic Acids and Polypeptides

2

NOVX polypeptides or biologically active portions thereof. Also included in the invention are nucleic acid fragments sufficient for use as hybridization probes to identify NOVX-encoding One aspect of the invention pertains to isolated nucleic acid molecules that encode amplification and/or mutation of NOVX nucleic acid molecules. As used herein, the term molecule may be single-stranded or double-stranded, but preferably is comprised double-'nucleic acid molecule" is intended to include DNA molecules (e.g., cDNA or genomic nucleolide analogs, and derivatives, fragments and homologs thereof. The nucleic acid DNA), RNA molecules (e.g., mRNA), analogs of the DNA or RNA generated using nucleic acids (e.g., NOVX mRNAs) and fragments for use as PCR primers for the stranded DNA

25

'mature" form of a polypeptide or protein disclosed in the present invention is the product of a An NOVX nucleic acid can encode a mature NOVX polypeptide. As used herein, a naturally occurring polypeptide or precursor form or proprotein. The naturally occurring

8

2

WO 02/33087

PCT/US01/32496

N remaining after removal of the N-terminal methionine. Alternatively, a mature form arising sequence from residue 1 to residue M is cleaved, would have the residues from residue M+1 to of a polypeptide or protein include the cleavage of the N-terminal methionine residuc encoded residue N remaining. Further as used herein, a "mature" form of a polypeptide or protein may which the gene product arises. Examples of such processing steps leading to a "mature" form residues 1 to N, where residue 1 is the N-terminal methionine, would have residues 2 through from a precursor polypeptide or protein having residues 1 to N, in which an N-terminal signal polypeptide, precursor or proprotein includes, by way of nonlimiting example, the full-length gene product, encoded by the corresponding gene. Alternatively, it may be defined as the naturally occurring processing steps as they may take place within the cell, or host cell, in by the initiation codon of an ORF, or the proteolytic cleavage of a signal peptide or leader arise from a step of post-translational modification other than a proteolytic cleavage event. nyristoylation or phosphorylation. In general, a mature polypeptide or protein may result polypeptide, precursor or proprotein encoded by an ORF described herein. The product sequence. Thus a mature form urising from a precursor polypeptide or protein that has "mature" form arises, again by way of nonlimiting example, as a result of one or more from the operation of only one of these processes, or a combination of any of them. Such additional processes include, by way of non-limiting example, glycosylation, S 2 2

probes are generally obtained from a natural or recombinant source, are highly specific, and The term "probes", as utilized herein, refers to nucleic acid sequences of variable much slower to hybridize than shorter-length oligomer probes. Probes may be single- or double-stranded and designed to have specificity in PCR, membrane-based hybridization detection of identical, similar, or complementary nucleic acid sequences. Longer length approximately, e.g., 6,000 nt, depending upon the specific use. Probes are used in the length, preferably between at least about 10 nucleotides (nt), 100 nt, or as many as technologies, or ELISA-like technologies. 20 25

the isolated NOVX nucleic acid molecules can contain less than about 5 kb, 4 kb, 3 kb, 2 kb, 1 The term "isolated" nucleic acid molecule, as utilized herein, is one, which is separated of the organism from which the nucleic acid is derived. For example, in various embodiments, kb, 0.5 kb or 0.1 kb of nucleotide sequences which naturally flank the nucleic acid molecule in genomic DNA of the celt/tissue from which the nucleic acid is derived (e.g., brain, hearl, liver, acid (i.e., sequences located at the 5'- and 3'-termini of the nucleic acid) in the genomic DNA from other nucleic acid molecules which are present in the natural source of the nucleic acid. Preferably, an "isolated" nucleic acid is free of sequences which naturally flank the nucleic 8

/3/490

spleen, etc.). Moreover, an "isolated" nucleic acid molecule, such as a cDNA molecule, can be substantially free of other cellular material or culture medium when produced by recombinant techniques, or of chemical precursors or other chemicals when chemically synthesized.

A nucleic acid molecule of the invention, e.g., a nucleic acid molecule having the nucleotide sequence SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, and 28, or a complement of this aforementioned nucleotide sequence, can be isolated using standard molecular biology techniques and the sequence information provided herein. Using all or a portion of the nucleic acid sequence of SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, and 28 as a hybridization probe, NOVX molecules can be isolated using standard hybridization and cloning techniques (e.g., as described in Sambrook, et al., (eds.), MOLECULAR CLONING: A LABORATORY MANUAL 2<sup>nd</sup> Ed., Cold Spring Harbor Laboratory Press, Cold Spring Harbor, NY, 1989; and Ausubel, et al., (eds.), CURRENT PROTOCOLS IN MOLECULAR BIOLOGY, John Wiley & Sons, New York, NY, 1993.)

5

A nucleic acid of the invention can be amplified using cDNA, mRNA or alternatively, genomic DNA, as a template and appropriate oligonucleotide primers according to standard PCR amplification techniques. The nucleic acid so amplified can be cloned into an appropriate vector and characterized by DNA sequence analysis. Furthermore, oligonucleotides corresponding to NOVX nucleotide sequences can be prepared by standard synthetic techniques, e.g., using an automated DNA synthesizer.

20

ᅜ

As used herein, the term "oligonucleotide" refers to a series of linked nucleotide residues, which oligonucleotide has a sufficient number of nucleotide bases to be used in a PCR reaction. A short oligonucleotide sequence may be based on, or designed from, a genomic or cDNA sequence and is used to amplify, confirm, or reveal the presence of an identical, similar or complementary DNA or RNA in a particular cell or lissue.

Oligonucleotides comprise portions of a nucleic acid sequence having about 10 nt, 50 nt, or 100 nt in length, preferably about 15 nt to 30 nt in length. In one embodiment of the invention, an oligonucleotide comprising a nucleic acid molecule less than 100 nt in length would further comprise at least 6 contiguous nucleotides SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, and 28, or a complement thereof. Oligonucleotides may be chemically synthesized and may also be used as probes.

25

In another embodiment, an isolated nucleic acid molecule of the invention comprises a nucleic acid molecule that is a complement of the nucleotide sequence shown in SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, and 28, or a portion of this nucleotide

೪

WO 02/33087 PCT/IIS01/32496

sequence (e.g., a fragment that can be used as a probe or primer or a fragment encoding a biologically-active portion of an NOVX polypeptide). A nucleic acid molecule that is complementary to the nucleotide sequence shown SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, or 28 is one that is sufficiently complementary to the nucleotide sequence shown SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, or 28 that it can hydrogen bond with little or no mismatches to the nucleotide sequence shown SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, and 28, thereby forming a stable duplex.

As used herein, the term "complementary" refers to Watson-Crick or Hoogsteen base pairing between nucleotides units of a nucleic acid molecule, and the term "binding" means the physical or chemical interaction between two polypeptides or compounds or associated polypeptides or compounds or combinations thereof. Binding includes ionic, non-ionic, van der Waals, hydrophobic interactions, and the like. A physical interaction can be either direct or indirect. Indirect interactions may be fitrough or due to the effects of another polypeptide or compound. Direct binding refers to interactions that do not take place through, or due to, the effect of another polypeptide or compound, but instead are without other substantial chemical intermediates.

Fragments provided herein are defined as sequences of at least 6 (contiguous) nucleic acids or at least 4 (contiguous) amino acids, a length sufficient to allow for specific hybridization in the case of nucleic acids or for specific recognition of an epitope in the case of amino acids, respectively, and are at most some portion less than a full length sequence. Fragments may be derived from any contiguous portion of a nucleic acid or amino acid sequence of choice. Derivatives are nucleic acid sequences or amino acid sequences formed from the native compounds either directly or by modification or partial substitution. Analogs are nucleic acid sequences or amino acid sequences that have a structure similar to, but not identical to, the native compound but differs from it in respect to certain components or side chains. Analogs may be synthetic or from a different evolutionary origin and may have a similar or opposite metabolic activity compared to wild type. Homologs are nucleic acid sequences or amino acid sequences of a particular gene that are derived from different species.

Derivatives and analogs may be full length or other than full length, if the derivative or analog contains a modified nucleic acid or amino acid, as described below. Derivatives or analogs of the nucleic acids or proteins of the invention include, but are not limited to, molecules comprising regions that are substantially homologous to the nucleic acids or proteins of the invention, in various embodiments, by at least about 70%, 80%, or 95% identity (with a preferred identity of 80-95%) over a nucleic acid or amino acid sequence of

identical size or when compared to an aligned sequence in which the alignment is done by a computer homology program known in the art, or whose encoding nucleic acid is capable of hybridizing to the complement of a sequence encoding the aforementioned proteins under stringent, moderately stringent, or low stringent conditions. See e.g. Ausubel, et al., CURRENT PROTOCOLS IN MOLECULAR BIOLOGY, John Wiley & Sons, New York, NY, 1993, and below.

S

2

A "homologous nucleic acid sequence" or "homologous amino acid sequence," or variations thereof, refer to sequences characterized by a homology at the nucleotide level or antino usid level as discussed above. Homologous nucleotide sequences encode those sequences coding for isoforms of NOVX polypeptides. Isoforms can be expressed in different tissues of the same organism as a result of, for example, alternative splicing of RNA.

Alternatively, isoforms can be encoded by different genes. In the invention, homologous nucleotide sequences include nucleotide sequences encoding for an NOVX polypeptide of species other than humans, including, but not limited to: vertebrates, and thus can include, e.g., frog, mouse, rat, rabbit, dog, cat cow, horse, and other organisms. Homologous nucleotide sequence also include, but are not limited to, naturally occurring alletic variations and mutations of the nucleotide sequences set forth herein. A homologous nucleotide sequence does not, however, include the exact nucleotide sequence encoding human NOVX protein. Homologous nucleic acid sequences that encode conservative amino acid substitutions (see below) in SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, and 28, as well as a polypeptide possessing NOVX biological activity. Various

13

An NOVX polypeptide is encoded by the open reading frame ("ORF") of an NOVX nucleic acid. An ORF corresponds to a nucleotide sequence that could potentially be translated into a polypeptide. A stretch of nucleic acids comprising an ORF is uninterrupted by a stop codon. An ORF that represents the coding sequence for a full protein begins with an ATG "start" codon and terminates with one of the three "stop" codons, namely, TAA, TAG, or TGA. For the purposes of this invention, an ORF may be any part of a coding sequence, with or without a start codon, a stop codon, or both. For an ORF to be considered as a good candidate for coding for a bona fide cellular protein, a minimum size requirement is often set, e.g., a stretch of DNA that would encode a protein of 50 amino acids or more.

25

hiological activities of the NOVX proteins are described below.

2

The nucleotide sequences determined from the cloning of the human NOVX genes allows for the generation of probes and primers designed for use in identifying and/or cloning NOVX homologues in other cell types, e.g. from other tissues, as well as NOVX homologues from other vertebrates. The probe/primer typically comprises substantially purified

8

PCT/US01/32496

11, 13, 15, 17, 19, 21, 23, 25, or 28, or of a naturally occurring mutant of SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, and 28.

Probes based on the human NOVX nucleotide sequences can be used to detect transcripts or genomic sequences encoding the same or homologous proteins. In various embodiments, the probe further comprises a label group attached thereto, e.g. the label group to can be a radioisotope, a fluorescent compound, an enzyme, or an enzyme co-factor. Such probes can be used as a part of a diagnostic test kit for identifying cells or tissues which misexpress an NOVX protein, such as by measuring a level of an NOVX-encoding nucleic acid in a sample of cells from a subject e.g., detecting NOVX mRNA levels or determining whether a genomic NOVX gene has been mutated or deleted.

"A polypeptide having a biologically-active portion of an NOVX polypeptide" refers to polypeptides exhibiting activity similar, but not necessarily identical to, an activity of a polypeptide of the invention, including mature forms, as measured in a particular biological assay, with or without dose dependency. A nucleic acid fragment encoding a "biologically-active portion of NOVX" can be prepared by isolating a portion SEQ ID NOS:1, 3, 5, 7, 9, 11, 20, 15, 17, 19, 21, 23, 25, or 28, that encodes a polypeptide having an NOVX biological activity (the biological activities of the NOVX proteins are described below), expressing the encoded portion of NOVX protein (e.g., by recombinant expression in vitro) and assessing the activity of the encoded portion of NOVX.

## NOVX Nucleic Acid and Polypeptide Variants

25

The invention further encompasses nucleic acid molecules that differ from the nucleotide sequences shown in SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, and 28 due to degeneracy of the genetic code and thus encode the same NOVX proteins as that encoded by the nucleotide sequences shown in SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, and 28. In another embodiment, an isolated nucleic acid molecule of the invention has a nucleotide sequence encoding a protein having an amino acid sequence shown in SEQ ID NOS:2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 27, or 29.

8

In addition to the human NOVX nucleotide sequences shown in SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, and 28, it will be appreciated by those skilled in the art that

polypeptides, are intended to be within the scope of the invention. preferably a vertebrate NOVX protein. Such natural allelic variations can typically result in result of natural allelic variation and that do not alter the functional activity of the NOVX variations and resulting amino acid polymorphisms in the NOVX polypeptides, which are the 1-5% variance in the nucleotide sequence of the NOVX genes. Any and all such nucleotide nucleic acid molecules comprising an open reading frame (ORF) encoding an NOVX protein polymorphism in the NOVX genes may exist among individuals within a population due to natural allelic variation. As used herein, the terms "gene" and "recombinant gene" refer to polypeptides may exist within a population (e.g., the human population). Such genetic DNA sequence polymorphisms that lead to changes in the amino acid sequences of the NOVX

ะ oDNAs of the invention can be isolated based on their homology to the human NOVX nucleic according to standard hybridization techniques under stringent hybridization conditions. acids disclosed herein using the human cDNAs, or a portion thereof, as a hybridization probe Nucleic acid molecules corresponding to natural allelic variants and homologues of the NOVX 11, 13, 15, 17, 19, 21, 23, 25, and 28 are intended to be within the scope of the invention. thus that have a nucleotide sequence that differs from the human SEQ ID NOS:1, 3, 5, 7, 9, Moreover, nuoleic acid molecules encoding NOVX proteins from other species, and

ಶ

20 60% homologous to each other typically remain hybridized to each other describe conditions for hybridization and washing under which nucleotide sequences at least embodiment, an isolated nucleic acid molecule of the invention hybridizes to the coding 50, 100, 250, 500, 750, 1000, 1500, or 2000 or more nucleotides in length. In yet another nucleic acid molecule comprising the nucleotide sequence of SEQ ID NOS:1, 3, 5, 7, 9, 11, invention is at least 6 nucleotides in length and hybridizes under stringent conditions to the region. As used herein, the term "hybridizes under stringent conditions" is intended to 13, 15, 17, 19, 21, 23, 25, and 28. In another embodiment, the nucleic acid is at least 10, 25 Accordingly, in another embodiment, an isolated nucleic acid molecule of the

ટ્ડ

using methods well known in the art for nucleic acid hybridization and cloning high stringency hybridization with all or a portion of the particular human sequence as a probe than human) or other related sequences (e.g., paralogs) can be obtained by low, moderate or Homologs (i.e., nucleic acids encoding NOVX proteins derived from species other

೪

different eircumstances. Longer sequences hybridize specifically at higher temperatures than other sequences. Stringent conditions are sequence-dependent and will be different in under which a probe, primer or oligonucleolide will hybridize to its target sequence, but to no As used herein, the phrase "stringent hybridization conditions" refers to conditions

> WO 02/33087 PCT/US01/32496

which the salt concentration is less than about 1.0 M sodium ion, typically about 0.01 to 1.0 M sequence at equilibrium. Since the target sequences are generally present at excess, at Tm, 50% of the probes are occupied at equilibrium. Typically, stringent conditions will be those in which 50% of the probes complementary to the target sequence hybridize to the target shorter sequences. Generally, stringent conditions are selected to be about 5 °C lower than the Tm is the temperature (under defined ionic strength, pH and nucleic acid concentration) at thormal melling point (Tm) for the specific sequence at a defined ionic strength and pH. The

5 oligonucleotides (e.g., 10 nt to 50 nt) and at least about 60°C for longer probes, primers and oligonucleotides. Stringent conditions may also be achieved with the addition of destabilizing pH 7.0 to 8.3 and the lemperature is at least about 30°C for short probes, primers or agents, such as formamide.

25 20 5 at 65°C, followed by one or more washes in 0.2X SSC, 0.01% BSA at 50°C. An isolated nature (e.g., encodes a natural protein) acid molecule refers to an RNA or DNA molecule having a nucleotide sequence that occurs in naturally-occurring nucleic acid molecule. As used herein, a "naturally-occurring" nucleic sequences SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, and 28, corresponds to a nucleic acid molecule of the invention that hybridizes under stringent conditions to the EDTA, 0.02% PVP, 0.02% Ficoll, 0.02% BSA, and 500 mg/ml denatured salmon sperm DNA hybridization in a high salt buffer comprising 6X SSC, 50 mM Tris-HCl (pH 7.5), 1 mM hybridized to each other. A non-limiting example of stringent hybridization conditions are (1989), 6.3.1-6.3.6. Preferably, the conditions are such that sequences at least about 65%, et al., (eds.), CURRENT PROTOCOLS IN MOLECULAR BIOLOGY, John Wiley & Sons, N.Y. 70%, 75%, 85%, 90%, 95%, 98%, or 99% homologous to each other typically remain Stringent conditions are known to those skilled in the art and can be found in Ausubel

8 1X SSC, 0.1% SDS at 37°C. Other conditions of moderate stringency that may be used are hybridization conditions are hybridization in 6X SSC, 5X Denhardt's solution, 0.5% SDS and well-known within the art. See, e.g., Ausubel, et al. (eds.), 1993, CURRENT PROTOCOLS IN 100 mg/ml denatured salmon sperm DNA at 55°C, followed by one or more washes in moderate stringency is provided. A non-limiting example of moderate stringency acid molecule comprising the nucleotide sequence of SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, and 28, or fragments, analogs or derivalives thereof, under conditions of In a second embodiment, a nucleic acid sequence that is hybridizable to the nucleic

22, 24, 27, or 29, even more preferably at least about 90% homologous to SEQ 🗅 NOS.2, 4, sequences SEQ ID NOS:2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 27, and 29. Preferably, the NOS:2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 27, and 29; more preferably at least about 70% preferably at least about 80% homologous to SEQ ID NOS:2, 4, 6, 8, 10, 12, 14, 16, 18, 20, protein encoded by the nucleic acid molecule is at least about 60% homologous to SEQ ID homologous SEQ ID NOS:2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 27, or 29; still more comprises an amino acid sequence at least about 45% homologous to the amino acid 5, 8, 10, 12, 14, 16, 18, 20, 22, 24, 27, or 29; and most preferably at least about 95% nomologous to SEQ ID NOS:2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 27, or 29. S

sequence of SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, and 28, such that one or more amino acid substitutions, additions or deletions are introduced into the encoded protein. protein of SEQ ID NOS:2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 27, or 29 can be created by infroducing one or more nucleotide substitutions, additions or deletions into the nucleotide An isolated nucleic acid molecule encoding an NOVX protein homologous to the

2

2

predicted, non-essential amino acid residues. A "conservalive amino acid substitution" is one Mutations can be introduced into SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, in which the amino acid residue is replaced with an amino acid residue having a similar side chain. Families of amino acid residues having similar side chains have been defined within nistidine), acidic side chains (e.g., aspartic acid, glutamic acid), uncharged polar side chains mutagenesis. Preferably, conservative amino acid substitutions are made at one or more 25, and 28 by standard techniques, such as site-directed mutagenesis and PCR-mediated the art. These families include amino acids with basic side chains (e.g., lysine, arginine, (e.g., Blycine, asparagine, glutamine, serine, threonine, tyrosine, cysteine), nonpolar side chains (e.g., alanine, valine, leucine, isoleucine, proline, phenylalanine, methionine,

20

amino acid residue in the NOVX protein is replaced with another amino acid residue from the tryptophan), beta-branched side chains (e.g., threonine, valine, isoleucine) and aromatic side hat retain activity. Following mutagenesis SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, chains (e.g., tyrosine, phenylalanine, tryptophan, histidine). Thus, a predicted non-essential name side chain family. Alternatively, in another embodiment, mutations can be introduced randomly along all or part of an NOVX coding sequence, such as by saturation mutagenesis, and the resultant mutants can be screened for NOVX biological activity to identify mutants 52

23, 25, and 28, the encoded protein can be expressed by any recombinant technology known in the art and the activity of the protein can be determined. 8

VLIM, HFY, wherein the letters within each group represent the single letter amino acid code of the following: CSA, ATV, SAG, STNK, STPA, SGND, SNDEQK, NDEQIIK, NEQHRK, substituted for each other. Likewise, the "weak" group of conserved residues may be any one wherein the single letter amino acid codes are grouped by those amino acids that may be conserved "weak" residues. The "strong" group of conserved amino acid residues may be any interactions. Substituted amino acids may be fully conserved "strong" residues or fully one of the following groups: STA, NEQK, NHQK, NDEQ, QHRK, MILV, MILF, HY, FYW, The relatedness of amino acid families may also be delermined based on side chain

protein:protein interactions with other NOVX proteins, other cell-surface proteins, or target protein or biologically-active portion thereof, (e.g. avidin proteins) and an NOVX ligand; or (iii) the ability of a mutant NOVX protein to bind to an intracellular biologically-active portions thereof, (ii) complex formation between a mutant NOVX protein In one embodiment, a mulant NOVX protein can be assayed for (i) the ability to form

5

regulate a specific biological function (a.g., regulation of insulin release). In yet another embodiment, a mutant NOVX protein can be assayed for the ability to

5

2

#### Antisense Nucleic Acids

or an entire NOVX coding strand, or to only a portion thereof. Nucleic acid molecules complementary to an NOVX nucleic acid sequence of SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, encoding fragments, homologs, derivatives and analogs of an NOVX protein of SEQ ID 17, 19, 21, 23, 25, and 28, are additionally provided. NOS:2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 27, or 29, or antisense nucleic acids comprise a sequence complementary to at least about 10, 25, 50, 100, 250 or 500 nucleotides to an mRNA sequence). In specific aspects, antisense nucleic acid molecules are provided that complementary to the coding strand of a double-stranded cDNA molecule or complementary fragments, analogs or derivatives thereof. An "antisense" nucleic acid comprises a nucleotide sequence that is complementary to a "sense" nucleic acid encoding a protein (e.g., that are hybridizable to or complementary to the nucleic acid molecule comprising the nucleotide sequence of SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, and 28, or Another aspect of the invention pertains to isolated antisense nucleic acid molecules

႘

2

Ś

In yet another embodiment, the antisense nucleic acid molecule of the invention is an α-anomeric nucleic acid molecule. An α-anomeric nucleic acid molecule forms specific double-stranded hybrids with complementary RNA in which, contrary to the usual β-units, the strands run parallel to each other. See, e.g., Gaultier, et al., 1987. Nucl. Acids Res. 15: 6625-6641. The antisense nucleic acid molecule can also comprise a 2'-o-methylribonucleotide (See, e.g., Inoue, et al., 1987. Nucl. Acids Res. 15: 6131-6148) or a chimeric RNA-DNA analogue (See, e.g., Inoue, et al., 1987. FEBS Lett. 215: 327-330.

2

### 25 Ribozymes and PNA Moieties

Nucleic acid modifications include, by way of non-limiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject.

8

In one embodiment, an antisense nucleic acid of the invention is a ribozyme. Ribozymes are catalytic RNA molecules with ribonuclease activity that are capable of cleaving a single-stranded nucleic acid, such as an mRNA, to which they have a complementary region. Thus, ribozymes (e.g., hammerhead ribozymes as described in

133

WO 02/33087 PCT/US01/32496

Haselhoff and Gerlach 1988. Nature 334: 585-591) can be used to catalytically cleave NOVX mRNA transcripts to thereby inhibit translation of NOVX mRNA. A ribozyme having specificity for an NOVX-encoding nucleic acid can be designed based upon the nucleotide sequence of an NOVX cDNA disclosed herein (i.e., SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17,

5 19, 21, 23, 25, and 28). For example, a derivative of a *Tetrallymena L*-19 IVS RNA can be constructed in which the nucleotide sequence of the active site is complementary to the nucleotide sequence to be cleaved in an NOVX-encoding mRNA. See, e.g., U.S. Patent 4,987,071 to Cech, et al. and U.S. Patent 5,116,742 to Cech, et al. NOVX mRNA can also be used to select a catalytic RNA having a specific ribonuclease activity from a pool of RNA molecules. See, e.g., Bartel et al., (1993) Science 261:1411-1418.

Allematively, NOVX gene expression can be inhibited by largeting nucleotide sequences complementary to the regulatory region of the NOVX nucleic acid (e.g., the NOVX promoter and/or enhancers) to form triple helical structures that prevent transcription of the NOVX gene in target cells. See, e.g., Helene, 1991. Anticancer Drug Des. 6: 569-84; Helene, et al. 1992. Ann. N.Y. Acad. Sci. 660: 27-36; Maher, 1992. Bioassays 14: 807-15.

2

In various embodiments, the NOVX nucleic acids can be modified at the base moiety, sugar moiety or phosphate backbone to improve, e.g., the stability, hybridization, or solubility of the molecule. For example, the deoxyribose phosphate backbone of the nucleic acids can be modified to generate peptide nucleic acids. See, e.g., Hyrup, et al., 1996. Bioorg Med Clem 4: 5-23. As used herein, the terms "peptide nucleic acids" or "PNAs" refer to nucleic acid mimics (e.g., DNA mimics) in which the deoxyribose phosphate backbone is replaced by a pseudopeptide backbone and only the four natural nucleobases are retained. The neutral backbone of PNAs has been shown to allow for specific hybridization to DNA and RNA under conditions of low ionic strength. The synthesis of PNA oligomers can be performed using standard solid phase peptide synthesis protocols as described in Hyrup, et al., 1996. supra; Perry-O'Keefe, et al., 1996. Proc. Natl. Acad. Sci. USA 93: 14670-14675.

PNAs of NOVX can be used in therapeutic and diagnostic applications. For example, PNAs can be used as antisense or antigene agents for sequence-specific modulation of gene expression by, e.g., inducing transcription or translation arrest or inhibiting replication. PNAs of NOVX can also be used, for example, in the analysis of single base pair mutations in a gene (e.g., PNA directed PCR clamping, as artificial restriction enzymes when used in combination with other enzymes, e.g., S<sub>1</sub> nucleases (See, Hyrup, et al., 1996, supra); or as probes or primers for DNA sequence and hybridization (See, Hyrup, et al., 1996, supra; Perry-O'Keefe, et al., 1996, supra)

ഉ

WO 02/33087

In another embodiment, PNAs of NOVX can be modified, e.g., to enhance their stability or cellular uptake, by attaching lipophilic or other helper groups to PNA, by the formation of PNA-DNA chimeras, or by the use of liposomes or other techniques of drug delivery known in the art. For example, PNA-DNA chimeras of NOVX can be generated that may combine the advantageous properties of PNA and DNA. Such chimeras allow DNA recognition enzymes (e.g., RNase H and DNA polymerases) to interact with the DNA portion

number of bonds between the nucleobases, and orientation (see, Hyrup, et al., 1996. supra).

The synthesis of PNA-DNA chimeras can be performed as described in Hyrup, et al., 1996.

supra and Finn, et al., 1996. Nucl Acids Res 24: 3357-3363. For example, a DNA chain can be synthesized on a solid support using standard phosphoramidite coupling chemistry, and modified nucleoside analogs, e.g., 5'-(4-methoxytrity))amino-5'-deoxy-thymidine

chimeras can be linked using linkers of appropriate lengths selected in terms of base stacking

while the PNA portion would provide high binding affinity and specificity. PNA-DNA

modified nuolooside analogs, e.g., 5'-(4-methoxytrityl)amino-5'-deoxy-thymidine phosphoramidite, can be used between the PNA and the 5' end of DNA. See, e.g., Mag, et al., 1989. Nucl Acid Res 17: 5973-5988. PNA monomers are then coupled in a stepwise manner to produce a chimeric molecule with a 5' PNA segment and a 3' DNA segment. See, e.g.. Finn, et al., 1996. supra. Alternatively, chimeric molecules can be synthesized with a 5' DNA segment and a 3' PNA segment. See, e.g., Petersen, et al., 1975. Bioorg. Med. Chem. Lett. 5:

peptides (a.g., for targeting host cell receptors in vivo), or agents facilitating transport across the cell membrane (sca, a.g., Letsinger, et al., 1989. Proc. Natl. Acad. Sci. U.S.A. 86: 6553-6556; Lemaitre, et al., 1987. Proc. Natl. Acad. Sci. 84: 648-652; PCT Publication No. WO88/09810) or the blood-brain barrier (see, e.g., PCT Publication No. WO 89/10134). In addition, oligonucleotides can be modified with hybridization triggered cleavage agents (see, e.g., Krol, et al., 1988. BioTechniques 6:938-976) or intervalating agents (sea, e.g., Zon, 1988. Pharm. Res. 5: 539-549). To this end, the oligonucleotide may be conjugated to another molecule, e.g., a peptide, a hybridization triggered cross-linking agent, a transport agent, a hybridization-triggered cleavage agent, and the like.

#### NOVX Polypeptides

엉

A polypeplide according to the invention includes a polypeptide including the amino acid sequence of NOVX polypeptides whose sequences are provided in SEQ ID NOS:2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 27, or 29. The invention also includes a mutant or variant

protein any of whose residues may be changed from the corresponding residues shown in SEC ID NOS:2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 27, or 29 while still encoding a protein that maintains its NOVX activities and physiological functions, or a functional fragment thereof.

In general, an NOVX variant that preserves NOVX-like function includes any variant

in which residues at a particular position in the sequence have been substituted by other amino acids, and further include the possibility of inserting an additional residue or residues between two residues of the parent protein as well as the possibility of deleting one or more residues from the parent sequence. Any amino acid substitution, insertion, or deletion is encompassed by the invention. In favorable circumstances, the substitution is a conservative substitution as the defined above.

One aspect of the invention pertains to isolated NOVX proteins, and biologicallyactive portions thereof, or derivatives, fragments, analogs or homologs thereof. Also provided
are polypeptide fragments suitable for use as immunogens to raise anti-NOVX antibodies. In
one embodiment, native NOVX proteins can be isolated from cells or tissue sources by an
appropriate purification scheme using standard protein purification techniques. In another
embodiment, NOVX proteins are produced by recombinant DNA techniques. Alternative to
recombinant expression, an NOVX protein or polypeptide can be synthesized chemically
using standard peptide synthesis techniques.

30 25 20 is substantially free of cellular material or other contaminating proteins from the cell or tissue biologically-active portion thereof is recombinantly-produced, it is also preferably one embodiment, the language "substantially free of cellular material" includes preparations of precursors or other chemicals when chemically synthesized. The language "substantially free more preferably less than about 10%, and most preferably less than about 5% of the volume of substantially free of culture medium, i.e., culture medium represents less than about 20%, most preferably less than about 5% of non-NOVX proteins. When the NOVX protein or non-NOVX proteins, still more preferably less than about 10% of non-NOVX proteins, and referred to herein as a "contaminating protein"), more preferably less than about 20% of NOVX proteins having less than about 30% (by dry weight) of non-NOVX proteins (also from cellular components of the cells from which it is isolated or recombinantly-produced. In of cellular material" includes preparations of NOVX proteins in which the protein is separated source from which the NOVX protein is derived, or substantially free from chemical the NOVX protein preparation An "isolated" or "purified" polypeptide or protein or biologically-active portion thereof

WO 02/33087

PCT/US01/32496

The language "substantially free of chemical precursors or other chemicals" includes preparations of NOVX proteins in which the protein is separated from chemical precursors or other chemicals that are involved in the synthesis of the protein. In one embodiment, the language "substantially free of chemical precursors or other chemicals" includes preparations of NOVX proteins having less than about 30% (by dry weight) of chemical precursors or non-NOVX chemicals, more preferably less than about 20% chemical precursors or non-NOVX chemicals, still more preferably less than about 10% chemical precursors or non-NOVX chemicals, and most preferably less than about 5% chemical precursors or non-NOVX chemicals.

Biologically-active portions of NOVX proteins include peptides comprising amino acid sequences sufficiently homologous to or derived from the amino acid sequences of the NOVX proteins (e.g., the amino acid sequence shown in SEQ ID NOS:2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 27, or 29) that include fewer amino acids than the full-length NOVX proteins, and exhibit at least one activity of an NOVX protein. Typically, biologically-active portions comprise a domain or motif with at least one activity of the NOVX protein. A biologically-active portion of an NOVX protein can be a polypeptide which is, for example, 10, 25, 50, 100 or more amino acid residues in length.

2

2

Moreover, other biologically-active portions, in which other regions of the protein are deleted, can be prepared by recombinant techniques and evaluated for one or more of the functional activities of a native NOVX protein.

20

In an embodiment, the NOVX protein has an amino acid sequence shown SEQ ID NOS:2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 27, or 29. In other embodiments, the NOVX protein is substantially homologous to SEQ ID NOS:2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 27, or 29, and retains the functional activity of the protein of SEQ ID NOS:2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 27, or 29, yet differs in amino acid sequence due to natural allelic variation or mulagenesis, as described in detail, below. Accordingly, in another embodiment, the NOVX protein is a protein that comprises an amino acid sequence at least about 45% homologous to the amino acid sequence SEQ ID NOS:2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24,

52

# Determining Homology Between Two or More Sequences

27, or 29, and retains the functional activity of the NOVX proteins of SEQ ID NOS:2, 4, 6, 8,

10, 12, 14, 16, 18, 20, 22, 24, 27, or 29.

8

To determine the percent homology of two amino acid sequences or of two nucleic acids, the sequences are aligned for optimal comparison purposes (e.g., gaps can be introduced

137

in the sequence of a first amino acid or nucleic acid sequence for optimal alignment with a second amino or nucleic acid sequence). The amino acid residues or nucleotides at corresponding amino acid positions or nucleotide positions are then compared. When a position in the first sequence is occupied by the same amino acid residue or nucleotide as the corresponding position in the second sequence, then the molecules are homologous at that position (i.e., as used herein amino acid or nucleic acid "homology" is equivalent to amino acid or nucleic acid "dentity").

The nucleic acid sequence homology may be determined as the degree of identity between two sequences. The homology may be determined using computer programs known in the art, such as GAP software provided in the GCG program package. See, Needleman und Wunsch, 1970. J Mol Biol 48: 443-453. Using GCG GAP software with the following settings for nucleic acid sequence comparison: GAP creation penalty of 5.0 and GAP extension penalty of 0.3, the coding region of the analogous nucleic acid sequences referred to above exhibits a degree of identity preferably of at least 70%, 75%, 80%, 85%, 90%, 95%, 98%, or 99%, with the CDS (encoding) part of the DNA sequence shown in SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, and 28.

The term "sequence identity" refers to the degree to which two polynucleotide or polypeptide sequences are identical on a residue-by-residue basis over a particular region of comparison. The term "percentage of sequence identity" is calculated by comparing two optimally aligned sequences over that region of comparison, determining the number of positions at which the identical nucleic acid base (e.g., A, T, C, G, U, or I, in the case of nucleic acids) occurs in both sequences to yield the number of matched positions, dividing the number of matched positions by the total number of positions in the region of comparison (i.e., the window size), and multiplying the result by 100 to yield the percentage of sequence identity. The term "enhancial clausity."

20

identity. The term "substantial identity" as used herein denotes a characteristic of a polynucleotide sequence, wherein the polynucleotide comprises a sequence that has at least 80 percent sequence identity, proferably at least 85 percent identity and often 90 to 95 percent sequence identity, more usually at least 99 percent sequence identity as compared to a reference sequence over a comparison region.

#### Chimeric and Fusion Proteins

2

The invention also provides NOVX chimeric or fusion proteins. As used herein, an NOVX "chimeric protein" or "fusion protein" comprises an NOVX polypeptide operatively-linked to a non-NOVX polypeptide. An "NOVX polypeptide" refers to a polypeptide having

to the NOVX protein, e.g., a protein that is different from the NOVX protein and that is having an amino acid sequence corresponding to a protein that is not substantially homologous 14, 16, 18, 20, 22, 24, 27, or 29, whereas a "non-NOVX polypeptide" refers to a polypeptide an amino acid sequence corresponding to an NOVX protein SEQ ID NOS:2, 4, 6, 8, 10, 12,

S

can be fused to the N-terminus or C-terminus of the NOVX polypeptide. protein, the term "operatively-linked" is intended to indicate that the NOVX polypeptide and comprises at least three biologically-active portions of an NOVX protein. 25 20 of the naturally occurring form of the protein has fewer side effects in a subject relative to embodiment, treatment of a subject with a variant having a subset of the biological activities biological effects can be elicited by treatment with a variant of limited function. In one member of a cellular signaling cascade which includes the NOVX protein. Thus, specific treatment with the naturally occurring form of the NOVX proteins the NOVX protein by, for example, competitively binding to a downstream or upstream the NOVX protein can inhibit one or more of the activities of the naturally occurring form of biological activities of the naturally occurring form of the NOVX protein. An antagonist of An agonist of the NOVX protein can retain substantially the same, or a subset of, the be generated by mutagenesis (e.g., discrete point mutation or truncation of the NOVX protein) NOVX agonists (i.e., mimetics) or as NOVX antagonists. Variants of the NOVX protein can The invention also pertains to variants of the NOVX proteins that function as either

activity. In one embodiment, a variegated library of NOVX variants is generated by combinatorial mutagenesis at the nucleic acid level and is encoded by a variegated gene (e.g., truncation mutants) of the NOVX proteins for NOVX protein agonist or antagonist or as NOVX antagonists can be identified by screening combinatorial libraries of mutants Variants of the NOVX proteins that function as either NOVX agonists (i.e., minetics)

မ

library. A variegated library of NOVX variants can be produced by, for example, enzymatically ligating a mixture of synthetic oligonucleotides into gene sequences such that a degenerate set of potential NOVX sequences is expressible as individual polypeptides, or alternatively, as a set of larger fusion proteins (e.g., for phage display) containing the set of NOVX sequences therein. There are a variety of methods which can be used to produce libraries of potential NOVX variants from a degenerate oligonucleotide sequence. Chemical synthesis of a degenerate gene sequence can be performed in an automatic DNA synthesizer, and the synthetic gene then ligated into an appropriate expression vector. Use of a degenerate set of genes allows for the provision, in one mixture, of all of the sequences encoding the desired set of potential NOVX sequences. Methods for synthesizing degenerate oligonucleotides are well-known within the art. See. e.g.. Narang, 1983. Tetrahedron 39: 3; Itakura, et al., 1984. Annu. Rev. Biochem. 53: 323; Itakura, et al., 1984. Science 198: 1056; Ike, et al., 1983. Nucl. Acids Res. 11: 477.

2

#### Polypeptide Libraries

2

In addition, libraries of fragments of the NOVX protein coding sequences can be used to generate a variegated population of NOVX fragments for screening and subsequent selection of variants of an NOVX protein. In one embodiment, a library of coding sequence fragments can be generated by treating a double stranded PCR fragment of an NOVX coding sequence with a nuclease under conditions wherein nicking occurs only about once per molecule, denaturing the double stranded DNA, renaturing the DNA to form double-stranded DNA that can include sense/antisense pairs from different nicked products, removing single stranded portions from reformed duplexes by treatment with S<sub>i</sub> nuclease, and ligating the resulting fragment library into an expression vector. By this method, expression libraries can be derived which encodes N-terminal and internal fragments of various sizes of the NOVX proteins.

ಜ

23

Various techniques are known in the art for screening gene products of combinatorial libraries made by point mutations or truncation, and for screening cDNA libraries for gene products having a selected property. Such techniques are adaptable for rapid screening of the gene libraries generated by the combinatorial mutagenesis of NOVX proteins. The most widely used techniques, which are amenable to high throughput analysis, for screening large gene libraries typically include cloning the gene library into replicable expression vectors, transforming appropriate cells with the resulting library of vectors, and expressing the combinatorial genes under conditions in which detection of a desired activity facilitates

8

WO 02/33087

PCT/US01/32496

isolation of the vector encoding the gene whose product was detected. Recursive ensemble mutagenesis (REM), a new technique that enhances the frequency of functional mutants in the libraries, can be used in combination with the screening assays to identify NOVX variants.

See, e.g., Arkin and Yourvan, 1992. Proc. Natl. Acad. Sci. USA 89: 7811-7815; Delgrave, et al., 1993. Protein Engineering 6:327-331.

#### Anti-NOVX Antibodies

Ś

Also included in the invention are antibodies to NOVX proteins, or fragments of NOVX proteins. The term "antibody" as used herein refers to immunoglobulin molecules and immunologically active portions of immunoglobulin (Ig) molecules, i.e., molecules that contain an antigen binding site that specifically binds (immunoreacts with) an antigen. Such antibodies include, but are not limited to, polyclonal, monoclonal, chimeric, single chain, Fab. Tab antibodies include, but are not limited to, polyclonal, monoclonal, chimeric, single chain, Fab. Tab antibodies include, but are not limited to, polyclonal, monoclonal, chimeric, single chain, Fab. Tab and Fab and Fab and an Fab expression library. In general, an antibody molecule obtained from humans relates to any of the classes IgG, IgM, IgA, IgE and IgD, which differ from one another by the nature of the heavy chain present in the molecule. Certain classes have subclasses as well, such as IgG, IgG, and others. Furthermore, in humans, the light chain may be a kappa chain or a lambda chain. Reference herein to antibodies includes a reference to all such classes, subclasses and types of human antibody species.

amino acid sequence of the full length protein and encompasses an epitope thereof such that an the antigenic peptide are regions of the protein that are located on its surface; commonly these immunogens. An antigenic peptide fragment comprises at least 6 amino acid residues of the generate antibodies that immunospecifically bind the antigen, using standard techniques for antigen, or a portion or fragment thereof, and additionally can be used as an immunogen to amino acid residues, or at least 30 amino acid residues. Preferred epilopes encompassed by An isolated NOVX-related protein of the invention may be intended to serve as an comprises at least 10 amino acid residues, or at least 15 amino acid residues, or at least 20 alternatively, the invention provides antigenic peptide fragments of the antigen for use as polyclonal and monoclonal antibody preparation. The full-length protein can be used or, antibody raised against the peptide forms a specific immune complex with the full length protein or with any fragment that contains the epitope. Preferably, the antigenic peptide are hydrophilic regions. 2 25 റ്റ

preferably contains one or more substances that inhibit the growth or survival of the unfused, immortalized cells. For example, if the parental cells lack the enzyme hypoxanthine guanine phosphoribosyl transferase (HGPRT or HPRT), the culture medium for the hybridomas typically will include hypoxanthine, aminopterin, and thymidine ("HAT medium"), which substances prevent the growth of HGPRT-deficient cells.

S

Preferred immortalized cell lines are those that fuse efficiently, support stable high level expression of antibody by the selected antibody-producing cells, and are sensitive to a medium such as HAT medium. More preferred inmortalized cell lines are murine myeloma lines, which can be obtained, for instance, from the Salk Institute Cell Distribution Center, San Diego, California and the American Type Culture Collection, Manassas, Virginia. Human myeloma and mouse-human heteromyeloma cell lines also have been described for the production of human monoclonal antibodies (Kozbor, J. Immunol., 133:3001 (1984); Brodeur et al., Monoclonal Antibody Production Techniques and Applications, Marcel Dekker, Inc., New York, (1987) pp. 51-63).

2

15

The culture medium in which the hybridoma cells are cultured can then be assayed for the presence of monoclonal antibodies directed against the antigen. Preferably, the binding specificity of monoclonal antibodies produced by the hybridoma cells is determined by immunoprecipitation or by an in vitro binding assay, such as radioimmunoassay (RIA) or enzyme-linked immunoabsorbent assay (ELISA). Such techniques and assays are known in the art. The binding affinity of the monoclonal antibody can, for example, be determined by the Scatchard analysis of Munson and Pollard, Anal. Bioclem., 107:220 (1980). Preferably, antibodies having a high degree of specificity and a high binding affinity for the target antigen are isolated.

20

After the desired hybridonna cells are identified, the clones can be subcloned by limiting dilution procedures and grown by standard methods. Suitable culture media for this purpose include, for example, Dulbecco's Modified Eagle's Medium and RPMI-1640 medium. Alternatively, the hybridoma cells can be grown in vivo as ascites in a mannal.

53

The monoclonal antibodies secreted by the subclones can be isolated or purified from the culture medium or ascites fluid by conventional immunoglobulin purification procedures such as, for example, protein A-Sepharose, hydroxylapatite chromatography, gel electrophoresis, dialysis, or affinity chromatography.

8

The monoclonal antibodies can also be made by recombinant DNA methods, such as those described in U.S. Patent No. 4,816,567. DNA encoding the monoclonal antibodies of the invention can be readily isolated and sequenced using conventional procedures (e.g., by

using oligonucleotide probes that are capable of binding specifically to genes encoding the heavy and light chains of murine untibodies). The hybridoma cells of the invention serve as a preferred source of such DNA. Once isolated, the DNA can be placed into expression vectors, which are then transfected into host cells such as simian COS cells, Chinese hamster overty

S (CHO) cells, or myeloma cells that do not otherwise produce immunoglobulin protein, to obtain the synthesis of monoclonal antibodies in the recombinant host cells. The DNA also can be modified, for example, by substituting the coding sequence for human heavy and light chain constant domains in place of the homologous murine sequences (U.S. Patent No. 4,816,567; Morrison, Nature 368, 812-13 (1994)) or by covalently joining to the

immunoglobulin coding sequence all or part of the coding sequence for a non-immunoglobulin polypeptide. Such a non-immunoglobulin polypeptide can be substituted for the constant domains of an antibody of the invention, or can be substituted for the variable domains of one antigen-combining site of an antibody of the invention to create a chimeric bivalent antibody.

# Humanized Antibodies

15

The antibodies directed against the protein antigens of the invention can further comprise humanized antibodies or human antibodies. These antibodies are suitable for administration to humans without engendering an immune response by the human against the administered immunoglobulin. Humanized forms of antibodies are chimeric immunoglobulins, immunoglobulin chains or fragments thereof (such as Fv, Fab, Fab', F(ab'), or other antigenbinding subsequences of antibodies) that are principally comprised of the sequence of a human immunoglobulin, and contain minimal sequence derived from a non-human immunoglobulin. Humanization can be performed following the method of Winter and co-workers (Jones et al., Nature, 321:522-525 (1986); Riechmann et al., Nature, 332:323-327 (1988); Verhoeyen et al., Science, 239:1534-1536 (1988)), by substituting rodent CDRs or CDR sequences for the corresponding sequences of a human antibody. (See also U.S. Patent No. 5,225,539.) In some

instances, Fv framework residues of the human immunoglobulin are replaced by corresponding non-human residues. Humanized antibodies can also comprise residues which are found neither in the recipient antibody nor in the imported CDR or framework sequences.

30 In general, the humanized antibody will comprise substantially all of at least one, and typically two, variable domains, in which all or substantially all of the CDR regions correspond to those of a non-human immunoglobulin and all or substantially all of the framework regions are those of a human immunoglobulin consensus sequence. The humanized antibody optimally also will comprise at least a portion of an immunoglobulin constant region (Fo), typically that

PCT/US01/32496

of a human immunoglobulin (Jones et al., 1986; Riechmann et al., 1988; and Presta, Curr. Op. Struct. Biol., 2:593-596 (1992)).

### **Human Antibodies**

Fully human antibodies relate to antibody molecules in which essentially the entire sequences of both the light chain and the heavy chain, including the CDRs, arise from human genes. Such antibodies are termed "human antibodies", or "fully human antibodies" herein. Human monoclonal antibodies can be prepared by the trioma technique; the human B-cell hybridoma technique (see Kozbor, et al., 1983 Immunol Today 4: 72) and the EBV hybridoma technique to produce human monoclonal antibodies (see Cole, et al., 1985 In: Monoclonal Antibodies may be utilized in the practice of the present invention and may be produced by using human hybridomas (see Cote, et al., 1983. Proc Natl Acad Sci USA 80: 2026-2030) or by transforming human B-cells with Epstein Barr Virus in vitro (see Cote, et al., 1985 In: MONOCLONAL ANTIBODIES AND CANCER THERAPY, Alan R. Liss, Inc., pp. 77-96).

5

monoclonal antibodies. Additionally, the genes encoding the immunoglobulins with human variable regions can be recovered and expressed to obtain the antibodies directly, or can be

from immortalized B cells derived from the animal, such as hybridomas producing

5

In addition, human antibodies can also be produced using additional techniques, including phage display libraries (Hoogenboom and Winter, *J. Mol. Biol.*, 227:381 (1991); Marks et al., *J. Mol. Biol.*, 222:581 (1991)). Similarly, human antibodies can be made by introducing human immunoglobulin loci into transgenic animals, e.g., mice in which the endogenous immunoglobulin genes have been partially or completely inactivated. Upon challenge, human antibody production is observed, which closely resembles that seen in humans in all respects, including gene rearrangement, assembly, and antibody repertoire. This approach is described, for example, in U.S. Patent Nos. 5,545,807; 5,545,806; 5,569,825; 5,625,126; 5,633,425; 5,661,016, and in Marks et al. (*BioTachnology* 10, 779-783 (1992)); Conberg et al. (*Vature* 368 856-859 (1994)); Morrison (*Nature* 368, 812-13 (1994)); Fishwild et al. (*Nature* 368 816-6190) 14, 845-51 (1996)); Neuberger (*Nature Biotechnology* 14, 826 (1996)); and Lonberg and fluszar (*Intern. Rev. Immunol.* 13 65-93 (1995)).

20

2

Human antibodies may additionally be produced using transgenic nonhuman animals which are modified so as to produce fully human antibodies rather than the animal's endogenous antibodies in response to challenge by an antigen. (See PCT publication WO94/02602). The endogenous genes encoding the heavy and light immunoglobulin chains in the nonhuman host have been incapacitated, and active loci encoding human heavy and light chain immunoglobulins are inserted into the host's genome. The human genes are

8

25

DNA segments. An animal which provides all the desired modifications is then obtained as progeny by crossbreeding intermediate transgenic animals containing fewer than the full complement of the modifications. The preferred embodiment of such a nonhuman animal is a mouse, and is termed the Xenonouse<sup>TM</sup> as disclosed in PCT publications WO 96/33735 and WO 96/34096. This animal produces B cells which secrete fully human immunoglobulins. The antibodies can be obtained directly from the animal after immunization with an immunogen of interest, as, for example, a preparation of a polyclonal antibody, or alternatively

further modified to obtain analogs of antibodies such as, for example, single chain Fv molecules.

An example of a method of producing a nonhuman host, exemplified as a mouse, lacking expression of an endogenous immunoglobulin heavy chain is disclosed in U.S. Patent No. 5,939,598. It can be obtained by a method including deleting the J segment genes from at least one endogenous heavy chain locus in an embryonic stem cell to prevent rearrangement of the locus and to prevent formation of a transcript of a rearranged immunoglobulin heavy chain locus, the deletion being effected by a targeting vector containing a gene encoding a selectable

A method for producing an antibody of interest, such as a human antibody, is disclosed in U.S. Patent No. 3,916,771. It includes introducing an expression vector that contains a nucleotide sequence encoding a heavy chain into one mammalian host cell in culture, introducing an expression vector containing a nucleotide sequence encoding a light chain into another mammalian host cell, and fusing the two cells to form a hybrid cell. The hybrid cell expresses an antibody containing the heavy chain and the light chain.

23

8

germ cells contain the gene encoding the selectable marker.

marker; and producing from the embryonic stem cell a transgenic mouse whose somatic and

In a further improvement on this procedure, a method for identifying a clinically relevant epitope on an immunogen, and a correlative method for selecting an antibody that binds immunospecifically to the relevant epitope with high affinity, are disclosed in PCT publication WO 99/53049.

# F<sub>nb</sub> Fragments and Single Chain Antibodies

엉

According to the invention, techniques can be adapted for the production of single-chain antibodies specific to an antigenic protein of the invention (see e.g., U.S. Palent

incorporated, for example, using yeast artificial chromosomes containing the requisite human

WO (12/334)87 PCT/USU1/32496

No. 4,946,778). In addition, methods can be adapted for the construction of F<sub>be</sub> expression libraries (see e.g., Huse, et al., 1989 Science 246: 1275-1281) to allow rapid and effective identification of monoclonal F<sub>ab</sub> fragments with the desired specificity for a protein or derivatives, fragments, analogs or homologs thereof. Antibody fragments that contain the idiotypes to a protein antigen may be produced by techniques known in the art including, but not limited to: (i) an F<sub>(ab)2</sub> fragment produced by pepsin digestion of an antibody molecule; (ii) an F<sub>ab</sub> fragment generated by reducing the disulfide bridges of an F<sub>(ab)2</sub> fragment; (iii) an F<sub>ab</sub> fragment generated by the treatment of the antibody molecule with papain and a reducing agent and (iv) F, fragments.

Bispecific Antibodies

2

Bispecific antibodies are monoclonal, preferably human or humanized, antibodies that have binding specificities for at least two different antigens. In the present case, one of the binding specificities is for an antigenic protein of the invention. The second binding target is any other antigen, and advantageously is a cell-surface protein or receptor or receptor subunit.

2

Methods for making bispecific antibodies are known in the art. Traditionally, the recombinant production of bispecific antibodies is based on the co-expression of two immunoglobulin heavy-chain/light-chain pairs, where the two heavy chains have different specificities (Milstein and Cuello, Nature, 305:537-539 (1983)). Because of the random assortment of immunoglobulin heavy and light chains, these hybridomas (quadromas) produce a polential mixture of ten different autibody molecules, of which only one has the correct bispecific structure. The purification of the correct molecule is usually accomplished by affinity chromatography steps. Similar procedures are disclosed in WO 93/08829, published 13 May 1993, and in Traunecker et al., 1991 EMBO J., 10:3655-3659.

ဥ

53

2

Antibody variable domains with the desired binding specificities (antibody-antigen combining siles) can be fused to immunoglobulin constant domain sequences. The fusion preferably is with an immunoglobulin heavy-chain constant domain, comprising at least part of the hinge, CH2, and CH3 regions. It is preferred to have the first heavy-chain constant region (CH1) containing the site necessary for light-chain binding present in at least one of the fusions. DNAs encoding the immunoglobulin heavy-chain fusions and, if desired, the immunoglobulin light chain, are inserted into separate expression vectors, and are cotransfected into a suitable host organism. For further details of generating bispecific antibodies see, for example, Suresh et al., Methods in Enzymology, 121:210 (1986).

ဓ္က

3

WO 02/33087 PCT/US01/32496

According to another approach described in WO 96/27011, the interface between a pair of antibody molecules can be engineered to maximize the percentage of heterodimers which are recovered from recombinant cell culture. The preferred interface comprises at least a part of the CH3 region of an antibody constant domain. In this method, one or more small amino acid side chains from the interface of the first antibody molecule are replaced with larger side chains (e.g. tyrosine or tryptophan). Compensatory "cavities" of identical or similar size to the large side chain(s) are created on the interface of the second antibody molecule by replacing large amino acid side chains with smaller ones (e.g. alanine or threonine). This provides a mechanism for increasing the yield of the heterodimer over other unwanted end-products such as homodimers.

Bispecific antibodies can be prepared as full length antibodies or antibody fragments (e.g. F(ab')), bispecific antibodies). Techniques for generating bispecific antibodies from antibody fragments have been described in the literature. For example, bispecific antibodies can be prepared using chemical linkage. Brennan et al., Science 229:81 (1985) describe a procedure wherein intact antibodies are proteolytically cleaved to generate F(ab'), fragments. These fragments are reduced in the presence of the dithiol comProhibiting agent sodium arsenite to stabilize vicinal dithiols and prevent intermolecular disulfide formation. The Fab' fragments generated are then converted to thionitrobenzoate (TNB) derivatives. One of the Fab'-TNB derivatives is then reconverted to the Fab'-thiol by reduction with mercaptoethylamine and is mixed with an equimolar amount of the other Fab'-TNB derivative to form the bispecific antibody. The bispecific antibodies produced can be used as agents for the selective immobilization of enzymes.

2

Additionally, Fab' fragments can be directly recovered from E. coli and chemically coupled to form bispecific antibodies. Shalaby et al., J. Exp. Med. 175:217-225 (1992) describe the production of a fully humanized bispecific antibody F(ab'); molecule. Each Fab' fragment was separately secreted from E. coli and subjected to directed chemical coupling in vitro to form the bispecific antibody. The bispecific antibody thus formed was able to bind to cells overexpressing the ErbB2 receptor and normal human T cells, as well as trigger the lytic activity of human cytotoxic lymphocytes against human breast tumor targets.

53

Various techniques for making and isolating bispecific antibody fragments directly from recombinant cell culture have also been described. For example, bispecific antibodies have been produced using leucine zippers. Kostelny et al., J. Immunol. 148(5):1547-1553 (1992). The leucine zipper peptides from the Fos and Jun proteins were linked to the fab' portions of two different antibodies by gene fusion. The antibody homodimers were reduced

(sFv) dimers has also been reported. See, Gruber et al., J. Immunol. 152:5368 (1994). sites. Another strategy for making bispecific antibody fragments by the use of single-chain Fv complementary  $V_L$  and  $V_H$  domains of another fragment, thereby forming two antigen-binding Accordingly, the  $V_{\mathsf{H}}$  and  $V_{\mathsf{L}}$  domains of one fragment are forced to pair with the comprise a heavy-chain variable domain ( $V_H$ ) connected to a light-chain variable domain ( $V_L$ ) by a linker which is too short to allow pairing between the two domains on the same chain. provided an alternative mechanism for making hispecific antibody fragments. The fragments technology described by Hollinger et al., Proc. Nall. Acad. Sci. USA 90:6444-6448 (1993) has This method can also be utilized for the production of antibody homodimers. The "diabody" at the hinge region to form monomers and then re-oxidized to form the antibody heterodimers

antibodies can be prepared. Tutt et al., J. Immunol. 147:60 (1991). Antibodies with more than two valencies are contemplated. For example, trispecific 5

bispecific antibody of interest binds the protein antigen described herein and further binds agent or a radionuclide chelator, such as EOTUBE, DPTA, DOTA, or TETA. Another anligen. These antibodies possess an antigen-binding arm and an arm which binds a cytotoxic to focus cellular defense mechanisms to the cell expressing the particular antigen. Bispecific antibodies can also be used to direct cytotoxic agents to cells which express a particular Fc receptors for IgG (FcγR), such as FcγR1 (CD64), FcγRII (CD32) and FcγRIII (CD16) so as of an immunoglobulin molecule can be combined with an arm which binds to a triggering lissue factor (TF). molecule on a leukocyte such as a T-cell receptor molecule (e.g. CD2, CD3, CD28, or B7), or which originates in the protein antigen of the invention. Alternatively, an anti-antigenic arm Exemplary bispecific antibodies can bind to two different epitopes, at least one of

For other suitable often provided by viral regulalory elements. For example, commonly used promoters are include pCDM8 (Seed, 1987. Nature 329: 840) and pMT2PC (Kaufinan, et al., 1987. EMBO cells using a mammalian expression vector. Examples of mammalian expression vectors In yet another embodiment, a nucleic acid of the invention is expressed in mammalian

WO 02/33087

expression systems for both prokaryotic and eukaryotic cells see, e.g., Chapters 16 and 17 of Harbor Laboratory, Cold Spring Harbor Laboratory Press, Cold Spring Harbor, N.Y., 1989. Sambrook, et al., MOLECULAR CLONING: A LABORATORY MANUAL. 2nd ed., Cold Spring

In another embodiment, the recombinant mammalian expression vector is capable of regulatory elements are known in the art. Non-limiting examples of suitable tissue-specific promoters include the albumin promoter (liver-specific; Pinkert, et al., 1987. Genes Dev. 1: lissue-specific regulatory elements are used to express the nucleic acid). Tissue-specific 268-277), lynphoid-specific promoters (Calame and Eaton, 1988. Adv. Inmunol, 43: directing expression of the nucleic acid preferentially in a particular cell type (e.g.,

235-275), in particular promoters of T cell receptors (Winoto and Baltimore, 1989. EMBO J. puncreas-specific promoters (Edlund, et al., 1985. Science 230: 912-916), and mammary Baltimore, 1983. Cell 33: 741-748), neuron-specific promoters (e.g., the neurofilament 8: 729-733) and immunoglobulins (Banerji, et al., 1983. Cell 33: 729-740; Queen and promoter; Byrne and Ruddle, 1989. Proc. Natl. Acad. Sci. USA 86; 5473-5477), 2

encompassed, e.g., the murine hox promoters (Kessel and Gruss, 1990. Science 249: 374-379) gland-specific promoters (e.g., milk whey promoter, U.S. Pat. No. 4,873,316 and European and the a-fetoprotein promoter (Campes and Tilghman, 1989. Genes Dev. 3: 537-546). Application Publication No. 264,166). Developmentally-regulated promoters are also

15

for expression (by transcription of the DNA molecule) of an RNA molecule that is antisense to unlisense orientation can be chosen that direct the continuous expression of the antisense RNA molecule in a variety of cell types, for instance viral promoters and/or enhancers, or regulatory sequences can be chosen that direct constitutive, tissue specific or cell type specific expression plasmid, phagemid or attenuated virus in which antisense nucleic acids are produced under the molecule of the invention cloned into the expression vector in an antisense orientation. That control of a high efficiency regulatory region, the activity of which can be determined by the is, the DNA molecule is operalively-linked to a regulatory sequence in a manner that allows expression using antisense genes see, e.g., Weintraub, et al., "Antisense RNA as a molecular The invention further provides a recombinant expression vector comprising a DNA NOVX mRNA. Regulatory sequences operatively linked to a nucleic acid cloned in the of antisense RNA. The antisense expression vector can be in the form of a recombinant cell type into which the vector is introduced. For a discussion of the regulation of gene tool for genetic analysis," Reviews-Trends in Genetics, Vol. 1(1) 1986. 20 23 8

Another aspect of the invention pertains to host cells into which a recombinant expression vector of the invention has been introduced. The terms "host cell" and

recombinant host cell" are used interchangeably herein. It is understood that such terms refer mutation or environmental influences, such progeny may not, in fact, be identical to the parent not only to the particular subject cell but also to the progeny or potential progeny of such a cell. Because certain modifications may occur in succeeding generations due to either cell, but are still included within the scope of the term as used herein.

S

A host cell can be any prokaryotic or eukaryotic cell. For example, NOVX protein can be expressed in bacterial cells such as  $E.\ coli,$  insect cells, yeast or mammalian cells (such as Chinese hamster ovary cells (CHO) or COS cells). Other suitable host cells are known to those skilled in the art.

Vector DNA can be introduced into prokaryotic or eukaryotic cells via conventional 'transfection" are inlended to refer to a variety of art-recognized techniques for introducing ransformation or transfection techniques. As used herein, the terms "transformation" and Coreign nucleic acid (e.g., DNA) into a host cell, including calcium phosphate or calcium chloride co-precipitation, DEAE-dextran-mediated transfection, lipofection, or 2

electroporation. Suitable methods for transforming or transfecting host cells can be found in Harbor Laboratory, Cold Spring Harbor Laboratory Press, Cold Spring Harbor, N.Y., 1989), Sambrook, et al. (MOLECULAR CLONING: A LABORATORY MANUAL. 2nd ed., Cold Spring and other laboratory manuals. 2

the foreign DNA into their genome. In order to identify and select these integrants, a gene that expression vector and transfection technique used, only a small fraction of cells may integrate host cells along with the gene of interest. Various selectable markers include those that confer encodes a selectable marker (e.g., resistance to antibiotics) is generally introduced into the resistance to drugs, such as G418, hygromycin and methotrexate. Nucleic acid encoding a For stable transfection of mammalian cells, it is known that, depending upon the 2

NOVX or can be introduced on a separate vector. Cells stably transfected with the introduced selectable marker can be introduced into a host cell on the same vector as that encoding nucleic acid can be identified by drug selection (e.g., cells that have incorporated the selectable marker gene will survive, while the other cells die). 25

A host cell of the invention, such as a prokuryotio or eukaryotic host cell in culture, can be used to produce (i.e., express) NOVX protein. Accordingly, the invention further provides ecombinant expression vector encoding NOVX protein has been introduced) in a suitable embodiment, the method comprises culturing the host cell of invention (into which a nethods for producing NOVX protein using the host cells of the invention. In one 2

PCT/US01/32496

medium such that NOVX protein is produced. In another embodiment, the method further comprises isolating NOVX protein from the medium or the host cell.

# Transgenic NOVX Animals

S

of the animal, prior to development of the animal. and an exogenous DNA molecule introduced into a cell of the animal,  $ag_{lpha}$ , an embryonic cell NOVX gene has been altered by homologous recombination between the endogenous gene or tissues of the transgente animal. As used herein, a "homologous recombinant animal" is a non-human animal, preferably a mammal, more preferably a mouse, in which an endogenous animal, thereby directing the expression of an encoded gene product in one or more cell types amphibians, etc. A transgene is exogenous DNA that is integrated into the genome of a cell evaluating modulators of NOVX protein activity. As used herein, a "transgenic animal" is a from which a transgenic animal develops and that remains in the genome of the mature transgenio animals include non-human primates, sheep, dogs, cows, goats, chickens, which one or more of the cells of the animal includes a transgene. Other examples of non-human animal, preferably a mammal, more preferably a rodent such as a rat or mouse, in for studying the function and/or activity of NOVX protein and for identifying and/or animals in which endogenous NOVX sequences have been altered. Such animals are useful NOVX sequences have been introduced into their genome or homologous recombinant Such host colls can then be used to create non-human transgenic animals in which exogenous animals. For example, in one embodiment, a host cell of the invention is a fertilized oocyte or an emhryonic stem cell into which NOVX protein-coding sequences have been introduced. The host cells of the invention can also be used to produce non-human transgenic

7

5

A transgenic animal of the invention can be created by introducing NOVX-encoding nucleic acid into the male pronuclei of a fertilized oocyte (e.g., by microinjection, retroviral infection) and allowing the oocyte to develop in a pseudopregnant female foster animal. The human NOVX oDNA sequences SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, and 28 can be introduced as a transgene into the genome of a non-human animal. Alternatively, a non-human homologue of the human NOVX gene, such as a mouse NOVX gene, can be isolated based on hybridization to the human NOVX oDNA (described further supra) and used as a transgene. Intronic sequences and polyadenylation signals can also be included in the transgene to increase the efficiency of expression of the transgene. A tissue-specific regulatory sequence(s) can be operably-linked to the NOVX transgene to direct expression of NOVX protein to particular cells. Methods for generating transgenic animals via embryo

မ

13

20

WO 02/33087 PCT/US01/32496

manipulation and microinjection, particularly animals such as mice, have become conventional in the art and are described, for example, in U.S. Patent Nos. 4,736,866; 4,870,009; and 4,873,191; and Hogan, 1986. In: MANIPULATING THE MOUSE EMBRYO, Cold Spring Harbor Laboratory Press, Cold Spring Harbor, N.Y. Similar methods are used for production of other transgenic animals. A transgenic founder animal can be identified based upon the presence of the NOVX transgene in its genome and/or expression of NOVX mRNA in tissues or cells of the animals. A transgenic founder animal can then be used to breed additional animals carrying the transgene. Moreover, transgenic animals carrying a transgene encoding NOVX protein can further be bred to other transgenic animals carrying other transgenes.

To create a homologous recombinant animal, a vector is prepared which contains at least a portion of an NOVX gene into which a deletion, addition or substitution has been introduced to thereby alter, e.g., functionally disrupt, the NOVX gene. The NOVX gene can be a human gene (e.g., the cDNA of SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, and 28), but more preferably, is a non-human homologue of a human NOVX gene. For example, a mouse homologue of human NOVX gene of SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, and 28 can be used to construct a homologous recombination vector suitable for altering an endogenous NOVX gene in the mouse genome. In one embodiment, the vector is designed such that, upon homologous recombination, the endogenous NOVX gene is functionally disrupted (i.e., no longer encodes a functional protein; also referred to as a "knock out" vector).

Alternatively, the vector can be designed such that, upon homologous recombination, the endogenous NOVX gene is mutated or otherwise altered but still encodes functional protein (e.g., the upstream regulatory region can be altered to thereby alter the expression of the endogenous NOVX protein). In the homologous recombination vector, the altered portion of the NOVX gene is flanked at its 5'- and 3'-termini by additional nucleic acid of the NOVX gene carried by the vector and an endogenous NOVX gene in an embryonic stem cell. The additional flanking NOVX nucleic acid is of sufficient length for successful homologous recombination with the endogenous gene. Typically, several kilobases of flanking DNA (both at the 5'- and 3'-termini) are included in the vector. Sec. e.g., Thomas, et al., 1987. Cell 51: 503 for a description of homologous recombination vectors. The vector is ten introduced into an embryonic stem cell line (e.g., by electroporation) and cells in which the introduced NOVX

PCT/US01/32496

gene has homologously-recombined with the endogenous NOVX gene are selected. See, e.g., Li, et al., 1992. Cell 69: 915.

The selected cells are then injected into a blastocyst of an animal (e.g., a mouse) to form aggregation climeras. See, e.g., Bradley, 1987. In: TERATOCARCINOMAS AND EMBRYONIC STEM CELLS: A PRACTICAL APPROACH, Robertson, ed. IRL, Oxford, pp. 113-152. A chimeric embryo can then be implanted into a suitable pseudopregnant female foster animal and the embryo brought to term. Progeny harboring the homologously-recombined DNA in their germ cells can be used to breed animals in which all cells of the animal contain the homologously-recombined DNA by germline transmission of the transgene. Methods for constructing homologous recombination vectors and homologous recombinant animals are described further in Bradley, 1991. Curr. Opin. Bioteclinol. 2: 823-829, PCT International Publication Nos.: WO 90/11354; WO 91/01140; WO 92/9968; and WO 93/04169.

2

2

In another embodiment, transgenic non-humans animals can be produced that contain selected systems that allow for regulated expression of the transgene. One example of such a system is the cre/loxP recombinase system of bacteriophage P1. For a description of the cre/loxP recombinase system of bacteriophage P1. For a description of the cre/loxP recombinase system, See, e.g., Lakso, et al., 1992. Proc. Natl. Acad. Sci. USA 89: 6232-6236. Another example of a recombinase system is the FLP recombinase system of Saccharomyces cerevisiae. See, O'Gorman, et al., 1991. Science 251:1351-1355. If a cre/loxP recombinase system is used to regulate expression of the transgene, animals containing transgenes encoding both the Cre recombinase and a selected protein are required. Such animals can be provided through the construction of "double" transgenic animals, e.g., by mating two transgenic animals, one containing a transgene encoding a selected protein and the other containing a transgene encoding a recombinase.

2

5

Clones of the non-human transgenic animals described herein can also be produced according to the methods described in Wilmut, et al., 1997. Nature 385: 810-813. In brief, a cell (e.g., a somatic cell) from the transgenic animal can be isolated and induced to exit the growth cycle and enter Go phase. The quiescent cell can then be fused, e.g., through the use of electrical pulses, to an enucleated oocyte from an animal of the same species from which the quiescent cell is isolated. The reconstructed oocyte is then cultured such that it develops to morula or blastocyte and then transferred to pseudopregnant female foster animal. The offspring bonne of this female foster animal will be a clone of the animal from which the cell (e.g., the somatic cell) is isolated.

The cell, for example, can of mammalian origin or a yeast cell membrane-hound form of NOVX protein, or a biologically-active portion thereof, on the cel In one embodiment, an assay is a cell-based assay in which a cell which expresses a

5

Ś

2

In another embodiment, an assay is a cell-based assay comprising contacting a cell expressing a membrane-bound form of NOVX protein, or a biologically-active portion thereof, on the cell surface with a test compound and determining the ability of the test compound to modulate (e.g., stimulate or inhibit) the activity of the NOVX protein or biologically-active portion thereof. Determining the ability of the test compound to modulate the activity of NOVX or a biologically-active portion thereof can be accomplished, for example, by determining the ability of the NOVX protein to bind to or interact with an NOVX target molecule. As used herein, a "target molecule" is a molecule with which an NOVX protein binds or interacts in nature, for example, a molecule on the surface of a cell which expresses an NOVX interacting protein, a molecule on the surface of a second cell, a molecule in the extracellular milieu, a molecule associated with the internal surface of a cell membrane or a oyloplasmic molecule. An NOVX target molecule can be a non-NOVX molecule or an

ಕ

25

20

NOVX protein or polypeptide of the invention. In one embodiment, an NOVX target molecule is a component of a signal transduction pathway that facilitates transduction of an extracellular signal (e.g. a signal generated by binding of a compound to a membrane-bound NOVX molecule) through the cell membrane and into the cell. The target, for example, can be a second intercellular protein that has catalytic activity or a protein that facilitates the association of downstream signaling molecules with NOVX.

Determining the ability of the NOVX protein to bind to or interact with an NOVX target molecule can be accomplished by one of the methods described above for determining direct binding. In one embodiment, determining the ability of the NOVX protein to bind to or interact with an NOVX target molecule can be accomplished by determining the activity of the target molecule. For example, the activity of the target molecule can be determined by detecting induction of a cellular second messenger of the target (i.e. intracellular Ca<sup>2+</sup>, diacylglycerol, IP<sub>3</sub>, etc.), detecting catalytic/enzymatic activity of the target an appropriate substrate, detecting the induction of a reporter gene (comprising an NOVX-responsive regulatory element operatively linked to a nucleic acid encoding a detectable marker, e.g., luciferase), or detecting a cellular response, for example, cell survival, celtular differentiation, or cell proliferation.

In yet another embodiment, an assay of the invention is a cell-free assay comprising contacting an NOVX protein or biologically-active portion thereof with a test compound and determining the ability of the test compound to bind to the NOVX protein or biologically-active portion thereof. Binding of the test compound to the NOVX protein can be determined either directly or indirectly as described above. In one such embodiment, the assay comprises contacting the NOVX protein or biologically-active portion thereof with a known compound which binds NOVX to form an assay mixture, contacting the assay mixture with a test compound, and determining the ability of the test compound to interact with an NOVX protein, wherein determining the ability of the test compound to preferentially bind to NOVX protein comprises determining the ability of the test compound to preferentially bind to NOVX protein comprises determining the ability of the test compound to preferentially bind to NOVX protein comprises determining the ability of the test compound to preferentially bind to NOVX protein comprises determining the ability of the test compound to preferentially bind to NOVX protein compound.

In still another embodiment, an assay is a cell-free assay comprising contacting NOVX protein or biologically-active portion thereof with a test compound and determining the ability of the test compound to modulate (e.g. stimulate or inhibit) the activity of the NOVX protein or biologically-active portion thereof. Determining the ability of the test compound to modulate the activity of NOVX can be accomplished, for example, by determining the ability of the NOVX protein to bind to an NOVX target nunlecule by one of the methods described

ä

above for determining direct binding. In an alternative embodiment, determining the ability of the test compound to modulate the activity of NOVX protein can be accomplished by determining the ability of the NOVX protein further modulate an NOVX target molecule. For example, the catalytic/enzymalic activity of the target molecule on an appropriate substrate can be determined as described, supra.

Ś

In yet another embodiment, the cell-free assay comprises contacting the NOVX protein or biologically-active portion thereof with a known compound which binds NOVX protein to form an assay mixture, contacting the assay mixture with a test compound, and determining the ability of the test compound to interact with an NOVX protein, wherein determining the ability of the test compound to interact with an NOVX protein, comprises determining the ability of the NOVX protein to preferentially bind to or modulate the activity of an NOVX target molecule.

2

The cell-free assays of the invention are amenable to use of both the soluble form or the membrane-bound form of NOVX protein. In the case of cell-free assays comprising the membrane-bound form of NOVX protein, it may be desirable to utilize a solubilizing agent such that the membrane-bound form of NOVX protein is maintained in solution. Examples of such solubilizing agents include non-ionic detergents such as n-octylglucoside, n-dodecylglucoside, n-dodecylmaltoside, octanoyl-N-methylglucamide, decanoyl-N-methylglucamide, Triton® X-100, Triton® X-114, Thesit®, lsofridecypoly(ethylene glycol ether)<sub>n</sub>, N-dodecyl-N,N-dimethyl-3-ammonio-1-propane sulfonate, 3-(3-cholamidopropyl)dimethylamminiol-1-propane sulfonate (CHAPS), or 3-(3-cholamidopropyl)dimethylamminiol-2-hydroxy-1-propane sulfonate (CHAPSO).

20

25

~

In more than one embodiment of the above assay methods of the invention, it may be desirable to immobilize either NOVX protein or its target molecule to facilitate separation of complexed from uncomplexed forms of one or both of the proteins, as well as to accommodate automation of the assay. Binding of a test compound to NOVX protein, or interaction of NOVX protein with a target molecule in the presence and absence of a candidate compound, can be accomplished in any vessel suitable for containing the reactants. Examples of such vessels include microtiter plates, test tubes, and micro-centrifuge tubes. In one embodiment, a fusion protein can be provided that adds a domain that allows one or both of the proteins to be bound to a matrix. For example, GST-NOVX fusion proteins or GST-target fusion proteins can be adsorbed onlo glutathione sepharose beads (Sigma Chemical, St. Louis, MO) or glutalhione derivatized microtiter plates, that are then combined with the test compound or the test compound and either the non-adsorbed target protein or NOVX protein, and the mixture is

ಜ

incubated under conditions conducive to complex formation (e.g., at physiological conditions for salt and pH). Following incubation, the beads or microtiter plate wells are washed to remove any unbound components, the matrix immobilized in the case of beads, complex determined either directly or indirectly, for example, as described, supra. Alternatively, the complexes can be dissociated from the matrix, and the level of NOVX protein binding or activity determined using standard techniques.

Other techniques for immobilizing proteins on matrices can also be used in the screening assays of the invention. For example, either the NOVX protein or its target molecule can be immobilized utilizing conjugation of biotin and streptuvidin. Biolinylated NOVX protein or target molecules can be prepared from biotin-NHS

(N-hydroxy-succinimide) using techniques well-known within the art (e.g., biotinylation kit, Pierce Chemicals, Rockford, III.), and immobilized in the wells of streptavidin-coated 96 well plates (Pierce Chemical). Alternatively, antibodies reactive with NOVX protein or target molecules, but which do not interfere with binding of the NOVX protein to its target molecule.

can be derivatized to the wells of the plate, and unbound target or NOVX protein trapped in the wells by antibody conjugation. Methods for detecting such complexes, in addition to those described above for the GST-immobilized complexes, include immunodetection of complexes using antibodies reactive with the NOVX protein or target molecule, as well as enzyme-linked assays that rely on detecting an enzymatic activity associated with the NOVX protein or target molecule.

In another embodiment, modulators of NOVX protein expression are identified in a method wherein a cell is contacted with a candidate compound and the expression of NOVX mRNA or protein in the cell is determined. The level of expression of NOVX mRNA or protein in the cell is determined. The level of expression of protein in the presence of the candidate compound. The candidate compound can then be identified as a modulator of NOVX mRNA or protein is greater (i.e., statistically significantly greater) in the presence of the candidate compound than in its absence, the candidate compound is identified as a stimulator of NOVX mRNA or protein specific absence, the candidate compound is identified as a stimulator of NOVX mRNA or protein species, in expression. Alternatively, when expression of NOVX mRNA or protein is less (statistically significantly less) in the presence of the candidate compound than in its absence, the candidate compound is identified as an inhibitor of NOVX mRNA or protein expression. The level of NOVX mRNA or protein expression. The level of NOVX mRNA or protein expression in the cells can be determined by methods described

herein for detecting NOVX mRNA or protein.

In yet another aspect of the invention, the NOVX proteins can be used as "bait proteins" in a two-hybrid assay or three hybrid assay (see, e.g., U.S. Patent No. 5,283,317; Zervos, ct al., 1993. Cell 72: 223-232; Madura, et al., 1993. J. Biol. Chem. 268: 12046-12054; Bartel, et al., 1993. Biotechniques 14: 920-924; Iwabuchi, et al., 1993. Oncogene 8: 1693-1696; and Brent WO 94/10300), to identify other proteins that bind to or interact with NOVX ("NOVX-binding proteins" or "NOVX-bp") and modulate NOVX activity. Such NOVX-binding proteins are also likely to be involved in the propagation of signals by the

NOVX proteins as, for example, upstream or downstream elements of the NOVX pathway.

S

8 ᅜ 5 detected and cell colonics containing the functional transcription factor can be isolated and domains of the transcription factor are brought into close proximity. This proximity allows used to obtain the cloned gene that encodes the protein which interacts with NOVX. transcription of a reporter gene (e.g., Lnc2) that is operably linked to a transcriptional interact, in vivo, forming an NOVX-dependent complex, the DNA-binding and activation domain of the known transcription factor. If the "bait" and the "prey" proteins are able to regulatory sile responsive to the transcription factor. Expression of the reporter gene can be unidentified protein ("prey" or "sample") is fused to a gene that codes for the activation other construct, a DNA sequence, from a library of DNA sequences, that encodes an which consist of separable DNA-binding and activation domains. Briefly, the assay utilizes gene encoding the DNA binding domain of a known transcription factor (e.g., GAL-4). In the two different DNA constructs. In one construct, the gene that codes for NOVX is fused to a The two-hybrid system is based on the modular nature of most transcription factors,

The invention further pertains to novel agents identified by the aforementioned screening assays and uses thereof for treatments as described herein.

#### Detection Assays

25

Portions or fragments of the cDNA sequences identified herein (and the corresponding complete gene sequences) can be used in numerous ways as polymuoleotide reagents. By way of example, and not of limitation, these sequences can be used to: (i) map their respective genes on a chromosome; and, thus, locate gene regions associated with genetic disease; (ii) identify an individual from a minute biological sample (tissue typing); and (iii) aid in forensic identification of a biological sample. Some of these applications are described in the subsections, below.

30

Chromosome Mapping

Once the sequence (or a portion of the sequence) of a gene has been isolated, this sequence can be used to map the location of the gene on a chromosomo. This process is called chromosome mapping. Accordingly, portions or fragments of the NOVX sequences, SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, and 28, or fragments or derivatives thereof, can be used to map the location of the NOVX genes, respectively, on a chromosomc. The mapping of the NOVX sequences to chromosomes is an important first step in correlating these sequences with genes associated with disease.

10 Briefly, NOVX genes can be mapped to chromosomes by preparing PCR primers (preferably 15-25 bp in length) from the NOVX sequences. Computer analysis of the NOVX, sequences can be used to rapidly select primers that do not span more than one exon in the genomic DNA, thus complicating the amplification process. These primers can then be used for PCR screening of somatic cell hybrids containing individual human chromosomes. Only those hybrids containing the human gene corresponding to the NOVX sequences will yield an amplified fragment.

Somatic cell hybrids are prepared by fusing somatic cells from different mammals (e.g., human and mouse cells). As hybrids of human and mouse cells grow and divide, they gradually lose human chromosomes in random order, but retain the mouse chromosomes. By using media in which mouse cells cannot grow, because they lack a particular enzyme, but in which human cells can, the one human chromosome that contains the gene encoding the needed enzyme will be retained. By using various media, panels of hybrid cell lines can be established. Each cell line in a panel contains either a single human chromosome or a small number of human chromosomes, and a full set of mouse chromosomes, allowing casy mapping of individual genes to specific human chromosomes. See, e.g., D'Eustachio, et al., 1983. Science 220: 919-924. Somatic cell hybrids containing only fragments of human chromosomes can also be produced by using human chromosomes with translocations and delations.

PCR mapping of somatic cell hybrids is a rapid procedure for assigning a particular sequence to a particular chromosome. Three or more sequences can be assigned per day using a single thermal cycler. Using the NOVX sequences to design oligonucleotide primers, sub-localization can be achieved with panels of fragments from specific chromosomes.

Fluorescence in situ hybridization (FISH) of a.DNA sequence to a metaphase chromosomal spread can further be used to provide a precise chromosomal location in one

step. Chromosome spreads can be made using cells whose division has been blocked in melaphase by a chemical like colcemid that disrupts the mitotic spindle. The chromosomes can be treated briefly with trypsin, and then stained with Giemsa. A pattern of light and dark bands develops on each chromosome, so that the chromosomes can be identified individually. The FISH technique can be used with a DNA sequence as short as 500 or 600 bases. However, clones larger than 1,000 bases have a higher likelihood of binding to a unique chromosomal location with sufficient signal intensity for simple detection. Preferably 1,000 bases, and more preferably 2,000 bases, will suffice to get good results at a reasonable amount of time. For a review of this technique, see, Verma, et al., HUMAN CHROMOSOMES: A MANUAL OF BASIC TECHNIQUES (Pergamon Press, New York 1988).

Reagents for chromosome mapping can be used individually to mark a single chromosome or a single site on that chromosome, or panels of reagents can be used for marking multiple sites and/or multiple chromosomes. Reagents corresponding to noncoding regions of the genes actually are preferred for mapping purposes. Coding sequences are more likely to be conserved within gene families, thus increasing the chance of cross hybridizations during chromosomal mapping.

2

2

Once a sequence has been mapped to a precise chromosomal location, the physical position of the sequence on the chromosome can be correlated with genetic map data. Such data are found, e.g., in McKusick, Mendellan Inhertrance in Man, available on-line through Johns Hopkins University Welch Medical Library). The relationship between genes and disease, mapped to the same chromosomal region, can then be identified through linkage analysis (co-inheritance of physically adjacent genes), described in, e.g., Egeland, et al., 1987. Nature, 325: 783-787.

20

52

(RFLPs).

25

Moreover, differences in the DNA sequences between individuals affected and unaffected with a disease associated with the NOVX gene, can be determined. If a mutation is observed in some or all of the affected individuals but not in any unaffected individuals, then the mutation is likely to be the causative agent of the particular disease. Comparison of affected and unaffected individuals generally involves first looking for structural alterations in the chromosomes, such as deletions or translocations that are visible from chromosome spreads or detectable using PCR based on that DNA sequence. Ultimately, complete sequencing of genes from several individuals can be performed to confirm the presence of a mutation and to distinguish mutations from polymorphisms.

39

#### Tissue Typing

The NOVX sequences of the invention can also be used to identify individuals from minute biological samples. In this technique, an individual's genomic DNA is digested with one or more restriction enzymes, and probed on a Southern blot to yield unique bands for identification. The sequences of the invention are useful as additional DNA markers for RPLP ("restriction fragment length polymorphisms," described in U.S. Patent No. 5,272,057).

Furthermore, the sequences of the invention can be used to provide an alternative technique that determines the actual base-by-base DNA sequence of selected portions of an individual's genome. Thus, the NOVX sequences described herein can be used to prepare two PCR primers from the 5'- and 3'-termini of the sequences. These primers can then be used to amplify an individual's DNA and subsequently sequence it.

Panels of corresponding DNA sequences from individuals, prepared in this manner, can provide unique individual identifications, as each individual will have a unique set of such 15 DNA sequences due to allelic differences. The sequences of the invention can be used to obtain such identification sequences from individuals and from tissue. The NOVX sequences of the invention uniquely represent portions of the human genome. Allelic variation occurs to some degree in the coding regions of these sequences, and to a greater degree in the noncoding regions. It is estimated that allelio variation between individual humans occurs with a frequency of about once per each 500 bases. Much of the allelic variation is due to single nucleotide polymorphisms (SNPs), which include restriction fragment length polymorphisms

Each of the sequences described herein can, to some degree, be used as a standard against which DNA from an individual can be compared for identification purposes. Because greater numbers of polymorphisms occur in the noncoding regions, fewer sequences are necessary to differentiate individuals. The noncoding sequences can comfortably provide positive individual identification with a panel of perhaps 10 to 1,000 primers that each yield a noncoding amplified sequence of 100 bases. If predicted coding sequences, such as those in SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, and 28 are used, a more appropriate number of primers for positive individual identification would be 500-2,000.

### Predictive Medicine

200

The invention also pertains to the field of predictive medicine in which diagnostic assays, prognostic assays, pharmacogenomics, and monitoring clinical trials are used for

prognostic (predictive) purposes to thereby treat an individual prophylactically. Accordingly, one aspect of the invention relates to diagnostic assays for determining NOVX protein and/or nucleic acid expression as well as NOVX activity, in the context of a biological sample (e.g., blood, serum, cells, tissue) to thereby determine whether an individual is afflicted with a disease or disorder, or is at risk of developing a disorder, associated with aberrant NOVX expression or activity. The disorders include metabolic disorders, diabetes, obesity, infectious disease, anorexia, cancer-associated cachexia, cancer, neurodegenerative disorders, Alzheimer's Disease, Parkinson's Disorder, immune disorders, and hematopoietic disorders,

S

and the various dyslipidemias, metabolic disturbances associated with obesity, the metabolic syndrome X and wasting disorders associated with chronic diseases and various cancers. The invention also provides for prognostic (or predictive) assays for determining whether an individual is at risk of developing a disorder associated with NOVX protein, nucleic acid expression or activity. For example, mutations in an NOVX gene can be assayed in a biological sample. Such assays can be used for prognostic or predictive purpose to thereby prophylactically treat an individual prior to the onset of a disorder characterized by or associated with NOVX protein, nucleic acid expression, or biological activity.

5

ᅜ

Another aspect of the invention provides methods for determining NOVX protein, nucleic acid expression or activity in an individual to thereby scleed appropriate therapeutic or prophylactic agents for that individual (referred to herein as "pharmacogenomics"). Pharmacogenomics allows for the solection of agents (e.g., drugs) for therapeutic or prophylactic treatment of an individual based on the genotype of the individual (e.g., the genotype of the individual examined to determine the ability of the individual to respond to a particular agent.)

8

Yet another aspect of the invention pertains to monitoring the influence of agents (e.g. drugs, compounds) on the expression or activity of NOVX in clinical trials.

25

These and other agents are described in further detail in the following sections

### Diagnostic Assays

ဗ

An exemplary method for delecting the presence or absence of NOVX in a biological sample involves obtaining a biological sample from a test subject and contacting the biological sample with a compound or an agent capable of detecting NOVX protein or nucleic acid (e.g., mRNA, genomic DNA) that encodes NOVX protein such that the presence of NOVX is detected in the biological sample. An agent for detecting NOVX mRNA or genomic DNA is a labeled nucleic acid probe capable of hybridizing to NOVX mRNA or genomic DNA. The

nucleic acid probe can be, for example, a full-length NOVX nucleic acid, such as the nucleic acid of SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, and 28, or a portion thereof, such as an oligonucleotide of at least 15, 30, 50, 100, 250 or 500 nucleotides in length and sufficient to specifically hybridize under stringent conditions to NOVX mRNA or genomic DNA. Other suitable probes for use in the diagnostic assays of the invention are described herein.

25 20 2 5 can be labeled with a radioactive marker whose presence and location in a subject can be detected by standard imaging techniques: include introducing into a subject a labeled anti-NOVX antibody. For example, the antibody Southern hybridizations. Furthermore, in vivo techniques for detection of NOVX protein immunofluorescence. In vitro techniques for detection of NOVX genomic DNA include immunosorbent assays (ELISAs), Western blots, immunoprecipitations, and hybridizations. In vitro techniques for detection of NOVX protein include enzyme linked subject. That is, the detection method of the invention can be used to detect NOVX mRNA vitro techniques for detection of NOVX mRNA include Northern hybridizations and in situ protein, or genomic DNA in a biological sample in vitro as well as in vivo. For example, in biological fluids isolated from a subject, as well as tissues, cells and fluids present within a end-labeling of a DNA probe with biotin such that it can be detected with fluorescentlydetection of a primary antibody using a fluorescently-labeled secondary antibody and substance to the probe or antibody, as well as indirect labeling of the probe or antibody by used. The term "labeled", with regard to the probe or antibody, is intended to encompass preferably, monoclonal. An intact antibody, or a fragment thereof (e.g., Fab or  $F(ab)_2$ ) can be labeled streptavidin. The term "biological sample" is intended to include tissues, cells and reactivity with another reagent that is directly labeled. Examples of indirect labeling include direct labeling of the probe or antibody by coupling (i.e., physically linking) a detectable protein, preferably an antibody with a detectable label. Antibodies can be polyclonal, or more An agent for detecting NOVX protein is an antibody capable of binding to NOVX

In one embodiment, the biological sample contains protein molecules from the test subject. Alternatively, the biological sample can contain mRNA molecules from the test subject or genomic DNA molecules from the test subject. A preferred biological sample is a peripheral blood leukocyte sample isolated by conventional means from a subject.

ಕ

In another embodiment, the methods further involve obtaining a control biological sample from a control subject, contacting the control sample with a compound or agent capable of detecting NOVX protein, mRNA, or genomic DNA, such that the presence of

NOVX protein, mRNA or genomic DNA is detected in the biological sample, and comparing the presence of NOVX protein, mRNA or genomic DNA in the control sample with the presence of NOVX protein, mRNA or genomic DNA in the test sample.

The invention also encompasses kits for detecting the presence of NOVX in a biological sample. For example, the kit can comprise: a labeled compound or agent capable of detecting NOVX protein or mRNA in a biological sample; means for determining the amount of NOVX in the sample; and means for comparing the amount of NOVX in the sample with a standard. The compound or agent can be packaged in a suitable container. The kit can further comprise instructions for using the kit to detect NOVX protein or nucleic acid.

S

### Prognostic Assays

2

13

The diagnostic methods described herein can furthennore be utilized to identify subjects having or at risk of developing a disease or disorder associated with aberrant NOVX expression or activity. For example, the assays described herein, such as the preceding diagnostic assays or the following assays, can be utilized to identify a subject having or at risk of developing a disorder associated with NOVX protein, nucleic acid expression or activity. Alternatively, the prognostic assays can be utilized to identify a subject having or at risk for developing a disease or disorder. Thus, the invention provides a method for identifying a disease or disorder associated with aberrant NOVX expression or activity in which a test sample is obtained from a subject and NOVX protein or nucleic acid is diagnostic for a subject having or at risk of developing a disease or disorder associated with aberrant NOVX expression or activity. As used herein, a "test sample" refers to a biological sample obtained from a subject of interest. For example, a test sample can be a biological fluid (e.g., serum), cell sample, or tissue.

20

25

Furthennore, the prognostic assays described herein can be used to determine whether a subject can be administered an agent (e.g., an agonist, antagonist, peptidomimetic, protein, peptide, nucleic acid, small molecule, or other drug candidate) to treat a disease or disorder associated with aberrant NOVX expression or activity. For example, such methods can be used to determine whether a subject can be effectively treated with an agent for a disorder. Thus, the invention provides methods for determining whether a subject can be effectively treated with an agent for a disorder associated with aberrant NOVX expression or activity in which a test sample is obtained and NOVX protein or nucleic acid is detected (e.g., wherein the presence of NOVX protein or nucleic acid is diagnostic for a subject that can be

ဗ္ဗ

ഉ

administered the agent to treat a disorder associated with aberrant NOVX expression or activity).

The methods of the invention can also be used to detect genetic lesions in an NOVX gene, thereby determining if a subject with the lesioned gene is at risk for a disorder characterized by aberrant cell proliferation and/or differentiation. In various embodiments, the nethods include detecting, in a sample of cells from the subject, the presence or absence of a genetic lesion characterized by at least one of an alteration affecting the integrity of a gene encoding an NOVX-protein, or the misexpression of the NOVX gene. For example, such genetic lesions can be detected by ascertaining the existence of at least one of: (i) a detetion of

10 one or more nucleotides from an NOVX gene; (ii) an addition of one or more nucleotides to an NOVX gene; (iii) a substitution of one or more nucleotides of an NOVX gene; (iv) a chromosomal rearrangement of an NOVX gene; (v) an alteration in the level of a messenger RNA transcript of an NOVX gene, (vi) aberrant modification of an NOVX gene, such as of the methylation pattern of the genomic DNA, (vii) the presence of a non-wild-type splicing pattern of a messenger RNA transcript of an NOVX gene, (viii) a non-wild-type level of an NOVX

15 of a messenger RNA transcript of an NOVX gene, (viii) a non-wild-type level of an NOVX protein, (ix) allelic loss of an NOVX gene, and (x) inappropriate post-translational modification of an NOVX protein. As described herein, there are a large number of assay techniques known in the art which can be used for delecting lesions in an NOVX gene. A preferred biological sample is a peripheral blood leukocyte sample isolated by conventional means from a subject. However, any biological sample containing nucleated cells may be used, including, for example, buccal mucosal cells.

In certain embodiments, detection of the lesion involves the use of a probe/primer in a polymerase chain reaction (PCR) (see, e.g., U.S. Patent Nos. 4,683,195 and 4,683,202), such as anchor PCR or RACE PCR, or, alternatively, in a ligation chain reaction (LCR) (see, e.g., Landegran, et al., 1988. Science 241: 1077-1080; and Nakazawa, et al., 1994. Proc. Natl. Acud. Sci. USA 91: 360-364), the latter of which can be particularly useful for detecting point mutations in the NOVX-gene (see, Abravaya, et al., 1995. Nucl. Acids Res. 23: 675-682). This method can include the steps of collecting a sample of cells from a patient, isolating nucleic acid (e.g., genomic, mRNA or both) from the cells of the sample, contacting the nucleic acid (e.g., genomic, mRNA or both) from the cells of the Sample, ontacting the nucleic acid detecting the presence or absence of an amplification product, or detecting the size of the amplification product and comparing the length to a control sample. It is anticipated

25

conjunction with any of the techniques used for detecting mutations described herein that PCR and/or LCR may be desirable to use as a preliminary amplification step in

method, followed by the detection of the amplified molecules using techniques well known to (sec. Lizardi, et al, 1988. BioTechnology 6: 1197), or any other nucleic acid amplification system (see, Kwoh, et al., 1989. Proc. Natl. Acad. Sci. USA 86: 1173-1177); QB Replicase Gualelli, et al., 1990. Proc. Natl. Acad. Sci. USA 87: 1874-1878), transcriptional amplification those of skill in the art. These detection schemes are especially useful for the detection of nucleic acid molecules if such molecules are present in very low numbers. Alternative amplification methods include: self sustained sequence replication (see,

2 5 No. 5,493,531) can be used to score for the presence of specific mutations by development or loss of a ribozyme cleavage site. the sample DNA. Moreover, the use of sequence specific ribozymes (see, e.g., U.S. Patent Differences in fragment length sizes between sample and control DNA indicates mutations in endonucleases, and fragment length sizes are determined by gel electrophoresis and compared control DNA is isolated, amplified (optionally), digested with one or more restriction identified by alterations in restriction enzyme cleavage patterns. For example, sample and In an alternative embodiment, mulations in an NOVX gene from a sample cell can be

USA 85: regions, the resulting material is then separated by size on denaturing polyacrylamide gels to and with piperidine in order to digest mismatched regions. After digestion of the mismatched DNA/DNA or RNA/DNA duplexes can be treated with hydroxylamine or osmium tetroxide nuclease to enzymatically digesting the mismatched regions. In other embodiments, either RNA/DNA duplexes can be treated with RNase and DNA/DNA hybrids treated with S1 4397; Saleeba, et al., 1992. Methods Enzymol. 217: 286-295. In an embodiment, the control

30 25 sequence, is hybridized to a cDNA or other DNA product from a test cell(s). The duplex is treated with a DNA mismatch repair enzyme, and the cleavage products, if any, can be at G/T mismatches. See, e.g., Hsu, et al., 1994. Carcinogenesis 15: 1657-1662. According to cleaves A at G/A mismatches and the thymidine DNA glycosylase from HeLa cells cleaves T an exemplary embodiment, a probe based on an NOVX sequence, e.g., a wild-type NOVX NOVX cDNAs obtained from samples of cells. For example, the mutY enzyme of E. coli mismatch repair" enzymes) in defined systems for detecting and mapping point mutations in proteins that recognize mismatched base pairs in double-stranded DNA (so called "DNA In still another embodiment, the mismatch cleavage reaction employs one or more

mutations in NOVX genes. For example, single strand conformation polymorphism (SSCP) In other embodiments, alterations in electrophoretic mobility will be used to identify

detected from electrophoresis protocols or the like. See. e.g., U.S. Patent No. 5,459,039.

may be used to detect differences in electrophoretic mobility between mutant and wild type nucleic acids. See, e.g., Oriti, et al., 1989. Proc. Natl. Acad. Sci. USA: 86: 2766; Cotton, 1993. Mutat. Res. 285: 125-144; Hayashi, 1992. Genet. Anal. Tech. Appl. 9: 73-79.
Single-stranded DNA fragments of sample and control NOVX nucleic acids will be denatured and allowed to renature. The secondary structure of single-stranded nucleic acids varies uccording to sequence, the resulting alteration in eleutrophoretic mobility enables the detection of even a single base change. The DNA fragments may be labeled or detected with labeled probes. The sensitivity of the assay may be enhanced by using RNA (rather than DNA), in which the secondary structure is more sensitive to a change in sequence. In one embodiment, the subject method utilizes heteroduplex analysis to separate double stranded heteroduplex molecules on the basis of changes in electrophoretic mobility. See, e.g., Kecn, et al., 1991. Trends Genet. 7: 5.

S

2

In yet another embodiment, the movement of mutant or wild-type fragments in polyacrylamide gels containing a gradient of denaturant is assayed using denaturing gradient gel electrophoresis (DGGE). See. e.g.. Myers, et al., 1985. Nature 313: 495. When DGGE is used as the method of analysis, DNA will be modified to insure that it does not completely denature, for example by adding a GC clamp of approximately 40 bp of high-melting GC-rich DNA by PCR. In a further embodiment, a temperature gradient is used in place of a denaturing gradient to identify differences in the mobility of control and sample DNA. See, e.g.. Rosenbaum and Reissner, 1987. Biophys. Chem. 265: 12753.

2

20

Examples of other techniques for detecting point mutations include, but are not limited to, selective oligonucleotide hybridization, selective amplification, or selective primer extension. For example, oligonucleotide primers may be prepared in which the known mutation is placed centrally and then hybridized to target DNA under conditions that permit hybridization only if a perfect match is found. See, e.g., Saiki, et al., 1986. Nature 324: 163; Saiki, et al., 1989. Proc. Natl. Acad. Sci. USA 86: 6230. Such altele specific oligonucleotides are hybridized to PCR amplified target DNA or a number of different mutations when the oligonucleotides are attached to the hybridizing membrane and hybridized with labeled target DNA.

25

Alternatively, allele specific amplification technology that depends on selective PCR amplification may be used in conjunction with the instant invention. Oligonucleotides used as primers for specific amplification may carry the mutation of interest in the center of the molecule (so that amplification depends on differential hybridization; see, e.g., Gibbs, et al., 1989. Mucl. Acids Res. 17: 2437-2448) or at the extreme 3-4erminus of one primer where,

8

≊

under appropriate conditions, mismatch can prevent, or reduce polymerase extension (see, e.g., Prossner, 1993. *Tiblech.* 11: 238). In addition it may be desirable to introduce a novel restriction site in the region of the mutation to create cleavage-based detection. See, e.g., Gasparini, et al., 1992. Mol. Cell Probes 6: 1. It is anticipated that in certain embodiments

amplification may also be performed using Taq ligase for amplification. Sea, e.g., Barany, 1991. Proc. Natl. Acad. Sci. USA 88: 189. In such cases, ligation will occur only if there is a perfect match at the 3'-terminus of the 5' sequence, making it possible to detect the presence of a known mutation at a specific site by looking for the presence or absence of amplification.

The methods described herein may be performed, for example, by utilizing

10 pre-packaged diagnostic kits comprising at least one probe nucleic acid or antibody reagent
described herein, which may be conveniently used, e.g., in clinical settings to diagnose
patients exhibiting symptoms or family history of a disease or illness involving an NOVX

pens.

Furthermore, any cell type or tissue, preferably peripheral blood leukocytes, in which

15 NOVX is expressed may be utilized in the prognostic assays described herein. However, any
biological sample containing nucleated cells may be used, including, for example, buccal
mucosal cells.

### Pharmacogenomics

Agents, or modulators that have a stimulatory or inhibitory effect on NOVX activity (e.g., NOVX gene expression), as identified by a screening assay described herein can be administered to individuals to treat (prophylactically or therapeutically) disorders (The disorders include metabolic disorders, diabetes, obesity, infectious disease, anorexia, cancerassociated cachexia, cancer, neurodegenerative disorders, Alzheimer's Disease, Parkinson's Disorder, immune disorders, and hematopoietic disorders, and the various dyslipidemias, metabolic disturbances associated with obesity, the metabolic syndrome X and wasting disorders associated with chronic diseases and various cancers.) In conjunction with such treatment, the pharmacogenomics (i.e., the study of the relationship between an individual's genotype and that individual's response to a foreign compound or drug) of the individual may

be considered. Differences in metabolism of therapeutics can lead to severe toxicity or therapeutic failure by altering the relation between dose and blood concentration of the pharmacologically active drug. Thus, the pharmacogenomics of the individual permits the selection of effective agents (e.g., drugs) for prophylactic or therapeutic treatments based on a consideration of the individual's genotype. Such pharmacogenomics can further be used to

individual can be determined to thereby select appropriate agent(s) for therapeulic or protein, expression of NOVX nucleic acid, or mutation content of NOVX genes in an determine appropriate dosages and therapeutic regimens. Accordingly, the activity of NOVX

sumple from a subject prior to administration of the agent; (ii) detecting the level of expression of an NOVX protein, mRNA, or genomic DNA in the preadministration sample; (iii) obtaining administration of the agent to the subject accordingly. For example, increased administration of the agent may be desirable to increase the expression or activity of NOVX to higher levels In one embodiment, the invention provides a method for monitoring the effectiveness screening assays described herein) comprising the steps of (i) obtaining a pre-administration mRNA, or genomic DNA in the post administration sample or samples; and (vi) altering the protein, mRNA, or genomic DNA in the pre-administration sample with the NOVX protein, post-administration samples; (v) comparing the level of expression or activity of the NOVX administration of the agent may be desirable to decrease expression or activity of NOVX to peptidomimetic, nucleio acid, small molecule, or other drug candidate identified by the than detected, i.e., to increase the effectiveness of the agent. Alternalively, decreased one or more post-administration samples from the subject; (iv) detecting the level of of treutment of a subject with an agent (e.g., an agonist, antagonist, protein, peptide, expression or activity of the NOVX protein, mRNA, or genomic DNA in the lower levels than detected, i.e., to decrease the effectiveness of the agent.

2

S

### Methods of Treatment

20

2

The invention provides for both prophylactic and therapeutic methods of treating a subject at risk of (or susceptible to) a disorder or having a disorder associated with aberrant NOVX expression or activity. The disorders include cardiomyopathy, atherosclerosis, hypertension, congenital heart defects, aortio stenosis, atrial septal defect (ASD), atrioventricular (A-V) canal defect, ductus arteriosus, pulmonary stenosis, subaortic stenosis, ventricular septal defect (VSD), valve disease, tuberous sclerosis, scleroderma, obesity, transplantation, adrenoleukodystrophy, congenital adrenal hyperplasia, prostate cancer, neoplasm; adenocarcinoma, lymphonia, uterus cancer, fertility, hemophilia, hypercoagulation, idiopathic thrombocytopenic purpura, immunodeficiencies, graft versus host disease, AIDS, bronchial asthma, Crohn's disease; multiple sclerosis, treatment of Albright Hereditary Ostocodystrophy, and other diseases, disorders and conditions of the like.

22

These methods of treatment will be discussed more fully, below.

## Disease and Disorders

8

Diseases and disorders that are characterized by increased (relative to a subject not suffering from the disease or disorder) tevels or biological activity may be treated with

185

Therapeutics that antagonize (i.e., reduce or inhibit) activity. Therapeutics that antagonize activity may be administered in a therapeutic or prophylactic manner. Therapeutics that may be utilized include, but are not limited to: (i) an aforementioned peptide, or analogs, derivatives, fragments or homologs thereof; (ii) antibodies to an aforementioned peptide; (iii)

- nucleic acids encoding an aforementioned peptide; (iv) administration of antisense nucleic acid and nucleic acid and nucleic acid stat are "dysfunctional" (i.e., due to a heterologous insertion within the coding sequences of coding sequences to an aforementioned peptide) that are utilized to "knockout" endogenous function of an aforementioned peptide by humologous recombination (see, e.g., Capecohi, 1989. Science 244: 1288-1292); or (v) modulators (i.e., inhibitors,
  - 10 agonists and antagonists, including additional peptide mimetic of the invention or antibodies specific to a peptide of the invention) that alter the interaction between an aforementioned peptide and its binding partner.

Diseases and disorders that are characterized by decreased (relative to a subject not suffering from the disease or disorder) levels or biological activity may be treated with 15 Therapeutics that increase (i.e., are agonists to) activity. Therapeutics that upregulate activity may be administered in a therapeutic or prophylactic manner. Therapeutics that may be utilized include, but are not limited to, an aforementioned peptide, or analogs, derivatives, fragments or homologs thereof; or an agonist that increases bioavailability.

Increased or decreased levels can be readily detected by quantifying peptide and/or RNA, by obtaining a patient tissue sample (e.g., from biopsy tissue) and assaying it in vitro for RNA or peptide levels, structure and/or activity of the expressed peptides (or mRNAs of an aforementioned peptide). Methods that are well-known within the art include, but are not limited to, immunoassays (e.g., by Western blot analysis, immunoprecipitation followed by sodium dodecyl sulfate (SDS) polyacrylamide gel electrophoresis, immunooytochemistry, etc.) and/or hybridization assays to detect expression of mRNAs (e.g., Northern assays, dot blots, in

### Prophylactic Methods

iilu hybridization, and the like).

In one aspect, the invention provides a method for preventing, in a subject, a disease or condition associated with an aberrant NOVX expression or activity, by administering to the subject an agent that modulates NOVX expression or at least one NOVX activity. Subjects at risk for a disease that is caused or contributed to by aberrant NOVX expression or activity can be identified by, for example, any or a combination of diagnostic or prognostic assays as described herein. Administration of a prophylactic agent can occur prior to the manifestation

of symptoms characteristic of the NOVX aberrancy, such that a disease or disorder is prevented or, alternatively, delayed in its progression. Depending upon the type of NOVX aberrancy, for example, an NOVX agonist or NOVX antagonist agent can be used for treating the subject. The appropriate agent can be determined based on screening assays described herein. The prophylactic methods of the invention are further discussed in the following subsections.

s

### Therapeutic Methods

5

combination of agents that modulates (e.g., up-regulates or down-regulates) NOVX expression or activity. In another embodiment, the method involves administering an NOVX protein or afflicted with a disease or disorder characterized by aberrant expression or activity of an vitro (e.g., by culturing the cell with the agent) or, alternatively, in vivo (e.g., by administering administering an agent (e.g., an agent identified by a screening assay described herein), or NOVX protein or nucleic acid molecule. In one embodiment, the method involves the agent to a subject). As such, the invention provides methods of treating an individual one embodiment, the agent stimulates one or more NOVX protein activity. Examples of such or activity for therapeutic purposes. The modulatory method of the invention involves nucleic acid molecule as therapy to compensate for reduced or aberrant NOVX expression or acid molecules and anti-NOVX antibodies. These modulatory methods can be performed in NOVX protein activity. Examples of such inhibitory agents include antisense NOVX nucleic that has been introduced into the cell. In another embodiment, the agent inhibits one or more stimulatory agents include active NOVX protein and a nucleic acid molecule encoding NOVX agent as described herein, such as a nucleic acid or a protein, a naturally-occurring cognate activity associated with the cell. An agent that modulates NOVX protein activity can be an contacting a cell with an agent that modulates one or more of the activities of NOVX protein ligand of an NOVX prolein, a peptide, an NOVX peptidomimetic, or other small molecule. In Another aspect of the invention pertains to methods of modulating NOVX expression

20

 $\overline{\mathbf{z}}$ 

Stimulation of NOVX activity is desirable in situations in which NOVX is abnormally downregulated and/or in which increased NOVX activity is likely to have a beneficial effect. One example of such a situation is where a subject has a disorder characterized by aberrant cell proliferation and/or differentiation (e.g., cancer or immune associated disorders). Another example of such a situation is where the subject has a gestational disease (e.g., preclampsia).

9

25

Determination of the Biological Effect of the Therapeutic

In various embodiments of the invention, suitable in vitro or in vivo assays are performed to determine the effect of a specific Therapeutic and whether its administration is indicated for treatment of the affected tissue.

In various specific embodiments, in vitro assays may be performed with representative colls of the type(s) involved in the patient's disorder, to determine if a given Therapeutic exerts the desired effect upon the cell type(s). Compounds for use in therapy may be tested in suitable animal model systems including, but not limited to rats, mice, chicken, cows, monkeys, rabbits, and the like, prior to testing in human subjects. Similarly, for in vivo testing, any of the animal model system known in the art may be used prior to administration to human subjects.

# Prophylactic and Therapculic Uses of the Compositions of the Invention

The NOVX nucleic acids and proteins of the invention are useful in potential prophylactic and therapeutic applications implicated in a variety of disorders including, but not limited to: metabolic disorders, diabetcs, obesity, infectious disease, anorexia, cancerassociated cancer, neurodegenerative disorders, Alzheimer's Disease, Parkinson's Disorder, immune disorders, hematopoietic disorders, and the various dyslipidemias, metabolic disturbances associated with obesity, the metabolic syndrome X and wasting disorders associated with chronic diseases and various cancers.

As an example, a cDNA encoding the NOVX protein of the invention may be useful in gene therapy, and the protein may be useful when administered to a subject in need thereof. By way of non-limiting example, the compositions of the invention will have efficacy for treatment of patients suffering from: metabolic disorders, diabetes, obesity, infectious disease, anorexia, cancer-associated cachexia, cancer, neurodegenerative disorders, Alzheimer's

Disease, Parkinson's Disorder, immune disorders, hematopoietic disorders, and the various

5 Disease, Parkinson's Disorder, immune disorders, hematopoietic disorders, and the various dyslipidemias.

Both the novel nucleic acid encoding the NOVX protein, and the NOVX protein of the invention, or fragments thereof, may also be useful in diagnostic applications, wherein the presence or amount of the nucleic acid or the protein are to be assessed. A further use could be as an anti-bacterial molecule (i.e., some peptides have been found to possess anti-bacterial properties). These materials are further useful in the generation of antibodies, which immunospecifically-bind to the novel substances of the invention for use in therapcutic or diagnostic methods.

ម

The invention will be further described in the following examples, which do not limit the scope of the invention described in the claims.

#### Examples

# Example 1. Identification of NOVX clones

S

2

2

The novel NOVX target sequences identified in the present invention were subjected to sequence available for the reverse primer. Table 11A shows the sequences of the PCR primers used for obtaining different clones. In each case, the sequence was examined, walking inward from the respective termini toward the coding sequence, until a suitable sequence that is either unique or highly selective was encountered, or, in the case of the reverse primer, until the stop sequences from other species. These primers were then employed in PCR amplification based on the following pool of human cDNAs: adrenal gland, bone marrow, brain - amygdala, brain the exon linking process to confirm the sequence. PCR primers were designed by starting at derived from exon linking was cloned into the pCR2.1 vector from Invitrogen. The resulting the most upstream sequence available, for the forward primer, and at the most downstream intestine, spinal cord, spleen, stomach, testis, thyroid, trachea, uterus. Usually the resulting codon was reached. Such primers were designed based on in silico predictions for the full cerebellum, brain - hippocampus, brain - substantia nigra, brain - thalamus, brain -whole, amplicons were gel purified, cloned and sequenced to high redundancy. The PCR product bacterial clone has an insert covering the entire open reading frame cloned into the pCR2.1 least 95% over 50 bp. In addition, sequence traces were evaluated manually and edited for vector. Table 17B shows a list of these bacterial clones. The resulting sequences from all database and with public ESTs. Fragments and ESTs were included as components for an assembly when the extent of their identily with another component of the assembly was at felul brain, fetal kidney, fetal liver, fetal lung, heart, kidney, lymphoma - Raji, mammary gland, pancreas, pituitary gland, placenta, prostate, salivary gland, skeletal muscle, small clones were assembled with themselves, with other fragments in CuraGen Corporation's length cDNA, part (one or more exons) of the DNA or protein sequence of the target sequence, or by translated homology of the predicted exons to closely related human corrections if appropriate. These procedures provide the sequence reported herein.

Physical clone: Exons were predicted by homology and the intronvexon boundaries were determined using standard genetic rules. Exons were further selected and refined by means of similarity determination using multiple BLAST (for example, tBlastN, BlastN, and BlastN) searches, and, in some instances, GeneScan and Grail. Expressed sequences from both public and proprietary databases were also added when available to further define and complete the gene sequence. The DNA sequence was then manually corrected for apparent inconsistencies thereby obtaining the sequences encoding the full-length protein.

Example 2. Quantitative expression analysis of clones in various cells and tissues

2

The quantitative expression of various clones was assessed using microfiter plates containing RNA samples from a variety of normal and pathology-derived cells, cell lines and tissues using real time quantitative PCR (RTQ PCR). RTQ PCR was performed on a Perkin-15 Elmer Biosystems ABI PRISM® 7700 Sequence Detection System. Various collections of samples are assembled on the plates, and referred to as Panel 1 (containing normal tissues and cancer cell lines), Panel 2 (containing samples derived from tissues from normal and cancer sources), Panel 3 (containing cancer cell lines), Panel 4 (containing cells and cells from normal tissues and cells related to inflammatory conditions), Panel 5D/51 (containing human tissues and cell lines with an emphasis on metabolic diseases), Panel CNSD.01 (containing samples from normal and diseased brains) and CNS\_neurodegeneration\_panel (containing

RNA integrity from all samples is controlled for quality by visual assessment of agarose gel electropherograms using 28S and 18S ribosomal RNA staining intensity ratio as a 25 guide (2:1 to 2.5:1 28s:18s) and the absence of low molecular weight RNAs that would be indicative of degradation products. Samples are controlled against genomic DNA

amples from normal and diseased brains).

These tissues histopathological assessment of tumor differentiation grade. Moreover, most samples include proximal) to the zone of surgery (designated "NAT", for normal adjacent tissue, in Table RR). In addition, RNA and cDNA samples were obtained from various human tissues derived from the original surgical pathology report that provides information regarding the clinical stage of matched margins" are evaluated by two independent pathologists (the surgical pathologists were ascertained to be free of disease and were purchased from various commercial sources the patient. These matched margins are taken from the tissue surrounding (i.e. immediately close cooperation with the National Cancer Institute's Cooperative Human Tissue Network (CHTN) or the National Disease Research Initiative (NDRI). The tissues are derived from composed of RNA or cDNA isolated from human tissue procured by surgeons working in margins" obtained from noncancerous tissue just adjacent to the tumor. These are termed numan malignancies und in cases where indicated many malignant tissues have "matched and again by a pathologists at NDRI or CHTN). This analysis provides a gross such as Clontech (Palo Alto, CA), Research Genetics, and Invitrogen. 2 2 25 20

#### PANEL 3D

The plates of Panel 3D are comprised of 94 cDNA samples and two control samples.

Specifically, 92 of these samples are derived from cultured human cancer cell lines, 2 samples

of human primary cerebellar tissue and 2 controls. The human cell lines are generally obtained from ATCC (American Type Culture Collection), NCI or the German tumor cell bank and fall into the following tissue groups: Squamous cell carcinoma of the tongue, breast cancer, prostate cancer, melanoma, epidermoid carcinoma, sarcomas, bladder carcinomas, pancreatic cancers, kidney cancers, leukemias/lymphomas, ovarian/uterine/cervical, gastric, colon, lung and CNS cancer cell lines. In addition, there are two independent samples of cerebellum. These cells are all cultured under standard recommended conditions and RNA extracted using the standard procedures. The cell lines in panel 3D and 1.3D are of the most common cell lines used in the scientific literature.

### anels 4D, 4R, and 4.1D

2

Panel 4 includes samples on a 96 well plate (2 control wells, 94 test samples) composed of RNA (Panel 4R) or cDNA (Panels 4D/4.1D) isolated from various human cell lines or tissues related to inflammatory conditions. Total RNA from control normal tissues such as colon and lung (Stratagene, La Jolla, CA) and thymus and kidney (Clontech) were employed. Total RNA from liver tissue from cirrhosis patients and kidney from lupus patients was obtained from BioChain (Biochain Institute, Inc., Hayward, CA). Intestinal tissue for RNA preparation from patients diagnosed as having Crohn's disease and ulcerative colitis was obtained from the National Disease Research Interchange (NDRI) (Philadelphia, PA).

2

Astrocytes, lung fibroblasts, dermal fibroblasts, coronary artery smooth muscle cells, small airway epithelium, bronchial epithelium, microvascular dermal endothelial cells, microvascular lung endothelial cells, human pulmonary aortic endothelial cells, human umbilical vein endothelial cells were all purchased from Clonetics (Walkersville, MLD) and grown in the media supplied for these cell types by Clonetics. These primary cell types were activated with various cytokines or combinations of cytokines for 6 and/or 12-14 hours, as indicated. The following cytokines were used; IL-1 beta at approximately 1-5 ng/ml, TNF alpha at approximately 5-10 ng/ml, IFN gamma at approximately 20-50 ng/ml, IL-4 at approximately 5-10 ng/ml, IL-9 at approximately 5-10 ng/ml l. L-9 at approximately 5-10 ng/ml. Snddhelial cells were sometimes starved for various times by culture in the basal media from Clonetics with 0.1% serum.

52

റ്റ

Mononuclear cells were prepared from blood of employees at CuraGen Corporation, using Ficoll. LAK cells were prepared from these cells by culture in DMEM 5% FCS (Hyclone), 100 μΜ non essential amino acids (Gibco/Life Technologies, Rockville, MD), 1

5-10 ng/ml for 6 hours. In some cases, mononuclear cells were cultured for 4-5 days in PMA and 1-2 µg/ml ionomycin, IL-12 at 5-10 ng/ml, IFN gamma at 20-50 ng/ml and IL-18 at mM sodium pyruvate (Gibco), mercaploethanol 5.5 x 10°5 M (Gibco), and 10 mM Hepes (Gibco) and Interleukin 2 for 4-6 days. Cells were then either activated with 10-20 ng/ml

5 Figoll and mixing the isolated mononuclear cells 1:1 at a final concentration of approximately mM sodium pyravate (Gibco), mercaptoethanol (5.5 x 10<sup>-5</sup> M) (Gibco), and 10 mM Hepes 2x106 cells/ml in DMEM 5% FCS (Hyclone), 100 µM non essential amino acids (Gibco), 1 samples were obtained by taking blood from two donors, isolating the mononuclear cells using were taken at 24, 48 and 72 hours for RNA preparation. MLR (mixed lymphocyte reaction) PHA (phytohemagglutinin) or PWM (pokeweed milogen) at approximately 5 µg/ml. Samples pyruvate (Gibco), mercaploethanol  $5.5 \times 10^{-5}$  M (Gibco), and 10 mM Hepes (Gibco) with DMEM 5% FCS (Hyclone), 100 µM non essential amino acids (Gibco), 1 mM sodium days for RNA preparation. (Gibco). The MLR was cultured and samples taken at various time points ranging from 1-7

ng/ml. Dendritic cells were also stimulated with anti-CD40 monoclonal antibody sodium pyruvate (Gibco), mercaploethanol 5.5 x 10° M (Gibco), 10 mM Hepcs (Gibco) and GMCSF and 5 ng/ml IL-4 for 5-7 days. Macrophages were prepared by culture of monocytes pyruvate (Giloco), mercaptoethanol 5.5 x 10.3 M (Giloco), and 10 mM Hepes (Giloco), 50 ng/m Monocytes were differentiated into dendritic cells by culture in DMEM 5% fetal calf serum selection columns and a Vario Magnet according to the manufacturer's instructions. (Pharmingen) at 10 µg/ml for 6 and 12-14 hours. dendritic cells were stimulated for 6 and 12-14 hours with lipopolysaccharide (LPS) at 100 10% AB Human Serum or MCSF at approximately 50 ng/ml. Monocytes, macrophages and for 5-7 days in DMEM 5% FCS (Hyolone), 100 μM non essential amino acids (Gibco), 1 mM (FCS) (Hyclone, Logan, UT), 100 μM non essential amino acids (Gibco), 1 mM sodium Monocytes were isolated from mononuclear cells using CD14 Miltenyi Beads, +ve VS

being CD45RA CD4 lymphocytes. CD45RA CD4, CD45RO CD4 and CD8 lymphocytes lymphocytes were isolated by depleting mononuclear cells of CD8, CD56, CD14 and CD19 were placed in DMEM 5% FCS (Hyclone), 100 µM non essential amino acids (Gibco), 1 mM CD45RO beads were used to isolate the CD45RO CD4 lymphocytes with the remaining cells cells using CD8, CD56, CD14 and CD19 Millenyi beads and positive selection. Then and a Vario Magnet according to the manufacturer's instructions. CD45RA and CD45RO CD4 mononuclear cells using CD4, CD8 and CD56 Miltenyi beads, positive VS selection columns CD4 lymphocytes, CD8 lymphocytes and NK cells were also isolated fron

೪

5 cultured in DMEM 5% FCS (Hyclone), 100 μM non essential amino acids (Gibco), 1 mM for 4 days and expanded as before. RNA was isolated 6 and 24 hours after the second DMEM 5% FCS (Hyclone), 100 µM non essential amino acids (Gibco), 1 mM sodium chronically activated CD8 lymphocytes, we activated the isolated CD8 lymphocytes for 4 days and IL-2 for 4-6 days before RNA was prepared. sodium pyruvate (Gibco), mercaptoethanol 5.5 x 10<sup>-5</sup> M (Gibco), and 10 mM Hepes (Gibco) activation and after 4 days of the second expansion culture. The isolated NK cells were pyruvate (Gibco), mercaptoethanol 5.5 x 10° M (Gibco), and 10 mM Hepes (Gibco) and IL-2 on anti-CD28 and anti-CD3 coated plates and then harvested the cells and expanded them in and plated at 10° cells/ml onto Falcon 6 well tissue culture plates that had been coated sodium pyruvate (Gibco), mercaploethanol 5.5 x 10°5 M (Gibco), and 10 mM Hepes (Gibco) The expanded CD8 cells were then activated again with plate bound anti-CD3 and anti-CD28 PBS. After 6 and 24 hours, the cells were harvested for RNA preparation. To prepare overnight with 0.5 µg/ml anti-CD28 (Pharmingen) and 3 ug/ml anti-CD3 (OKT3, ATCC) in

2 approximately 10 µg/ml and IL-4 at 5-10 ng/ml. Cells were harvested for RNA preparation at Hepes (Giboo). To activate the cells, we used PWM at 5  $\mu g/ml$  or anti-CD40 (Pharmingen) at dissecting seissors and then passed through a sieve. Tonsil cells were then spun down and 24,48 and 72 hours. (Gibco), 1 mM sodium pyruvate (Gibco), mercaptoethanol 5.5 x 10<sup>-5</sup> M (Gibco), and 10 mM resupended at 10<sup>6</sup> cells/ml in DMEM 5% FCS (Hyclone), 100 μM non essential amino acids To obtain B cells, tonsils were procured from NDRI. The tonsil was cut up with sterile

20

y 23 days with anti-CD28/OKT3 and cytokines as described above, but with the addition of anting/m1). Following this, the activated Th1, Th2 and Tr1 lymphocytes were re-stimulated for S pyτυνate (Gibco), mercaptoethanol 5.5  $_{
m X}$  10  $^{
m S}$  M (Gibco), 10 mM Hepes (Gibco) and 1L-2 (1 days in DMEM 5% FCS (Hyclone), 100 μM non essential amino acids (Gibco), 1 mM sodium activated Th1, Th2 and Tr1 lymphocytes were washed once in DMEM and expanded for 4-7 used to direct to Th2 and IL-10 at 5 ng/ml was used to direct to Tr1. After 4-5 days, the Dg/ml) were used to direct to Th1, while IL-4 (5 ng/ml) and anti-IFN gamma (1 Dg/ml) were <sup>5</sup>M (Gibco), 10 mM Hepes (Gibco) and IL-2 (4 ng/ml). IL-12 (5 ng/ml) and anti-IL4 (1 non essential amino acids (Gibco), 1 mM sodium pyruvate (Gibco), mercaptoethanol 5.5  $\times$  10: German Town, MD) were cultured at 10 -10 cells/ml in DMEM 5% FCS (Hyclone), 100 μΜ and then washed twice with PBS. Umbilical cord blood CD4 lymphocytes (Poictic Systems, were coated overnight with 10  $\mu g/ml$  anti-CD28 (Pharmingen) and 2  $\mu g/ml$  OKT3 (ATCC), To prepare the primary and secondary Th1/Th2 and Tr1 cells, six-well Falcon plates

lymphocytes were maintained in this way for a maximum of three cycles. RNA was prepared from primary and secondary Th1, Th2 and Tr1 after 6 and 24 hours following the second and third activations with plate bound anti-CD3 and anti-CD28 mAbs and 4 days into the second CD95L (1 Dg/ml) to prevent apoptosis. After 4-5 days, the Th1, Th2 and Tr1 lymphocytes were washed and then expanded again with IL-2 for 4-7 days. Activated Th1 and Th2 and third expansion cultures in Interleukin 2.

S

2

Hepes (Gibco). RNA was either prepared from resting cells or cells activated with PMA at 10 ng/ml and ionomycin at 1 µg/ml for 6 and 14 hours. Keratinocyte line CCD106 and an airway cells/ml for 8 days, changing the media every 3 days and adjusting the cell concentration to 5 ng/ml IL-1 beta, while NCI-H292 cells were activated for 6 and 14 hours with the following CCD1106 cells were activated for 6 and 14 hours with approximately 5 ng/ml TNF alpha and x10° cells/ml. For the culture of these cells, we used DMEM or RPMI (as recommended by epithelial tumor line NCI-H292 were also obtained from the ATCC. Both were cultured in The following leukocyte cells lines were obtained from the ATCC: Ramos, EOL-1, (Gibco), 1 mM sodium pyruvate (Gibco), mercaptoethanol 5.5  $\times$   $10^{-5}$  M (Gibco), 10 mM KU-812. EOL cells were further differentiated by culture in 0.1 mM dbcAMP at  $5\,\mathrm{x}10^5$ he ATCC), with the addition of 5% FCS (Hyclone), 100 µM non essential amino acids DMEM 5% FCS (Hyclone), 100 µM non essential amino acids (Gibco), 1 mM sodium pyravate (Gibco), mercaptoethanol 5.5 x 10.3 M (Gibro), and 10 mM Hepes (Gibco). cytokines: 5 ng/ml  $\rm LL$ -4, 5 ng/ml  $\rm LL$ -9, 5 ng/ml  $\rm LL$ -13 and 25 ng/ml  $\rm IFN$  gamma.

Panel CNS\_Neurodegeneration\_V1.0

8

lest samples comprised of cDNA isolated from postmortem human brain tissue obtained from The plates for Panel CNS\_Neurodegeneration\_V1.0 include two control wells and 47 the Harvard Brain Tissue Resource Center (McLean Hospital) and the Humun Brain and

Spinal Fluid Resource Center (VA Greater Los Angeles Healthcare System). Brains are removed from calvaria of donors between 4 and 24 hours after death, sectioned by neuroanatomists, and frozen at -80°C in liquid nitrogen vapor. All brains are sectioned and examined by neuropathologists to confirm diagnoses with clear associated neuropathology.

Disease diagnoses are taken from patient records. The panel contains six brains from Alzheimer's disease (AD) pateins, and eight brains from "Normal controls" who showed no evidence of dementia prior to death. The eight normal control brains are divided into two categories: Controls with no dementia and no Alzheimer's like pathology (Controls) and controls with no dementia but evidence of severe Alzheimer's like pathology, (specifically senile plaque load rated as level 3 on a scale of 0-3; 0 = no evidence of plaques, 3 = severe AD senile plaque load). Within each of these brains, the following regions are represented: hippocampus, temporal cortex (Broddmann Area 21), parietal cortex (Broddmann area 17), and occipital cortex (Broddmann area 17). These regions were chosen to encompass all levels of neurodegeneration in AD. The hippocampus is a region of early and severe neuronal loss in AD; the temporal cortex is known to show neurodegeneration in AD after the hippocampus; the parietal cortex is spared in AD and therefore acts as a "control" region within AD patients. Not all brain regions are represented in all cases.

Expression of gene NOVIa and variant NOVIa was assessed using the primer-probe sets Ag4164, Ag1313b, Ag2197, and Ag708 described in Tables 12, 13, 14, and 15. Plcaso note that Ag4164 contains a single mismatch in the proba relative to the NOVIa and NOVId

 $\mathbf{z}$ 

sequences. This mismatch is not predicted to alter the RTQ-PCR results. Results from RTQ-PCR runs are shown in Tables 16, 17, 18, and 19.

Panel 1.2 Summary <u>Ag708</u> Expression of the NOV1a gene was assessed in two independent experiments using the same probe/primer set. There appears to be poor concordance between runs for some tissues but there is good concordance for others; only those results that are in agreement will be discussed here. In both experiments, highest expression of the NOV1a gene in a sample derived from a glioblastoma cell line (CTs = 24-26). Among normal tissues derived from the central nervous system, the NOV1a gene is also expressed at moderate levels in the cerebral cortex, cerebellum and hippocampus.

Ś

Among lissues with metabolic function, the NOV1a gene is expressed in the pancreas. Thus, this gene may be involved in the pathogenesis and/or treatment of diseases involving the pancreas, such as puncreatitis and diabetes. In addition, NOV1a gene expression is decreased in a pancreatic cancer cell line.

9

The NOV1a gene appears to be overexpressed in fetal kidney when compared to the adult kidney. This result suggests that the NOV1a gene could be used to distinguish between adult and fetal kidney tissue and that this gene may play an important role in kidney development, growth and survival. Furthermore, NOV1a gene expression is higher in normal ovary, mammary gland and lung when compared to the cancer cell lines obtained from these lissues suggesting that this can be used as a marker to differentiate malignant and normal

Panel 1.3D Summary <u>Ag708/Ag1313b/Ag2197</u> Three experiments with three different probe and primer sets produced results that were in very good agreement. One run, designated 1.3dx4tm5365t, appears to have lower absolute expression, but produces the same expression profile as the other two experiments. Highest expression of the NOV1A gene in all three runs is seen in a sample derived from a CNS cancer cell line (CTs=27). Certain glioblastoma and astrocytoma cell lines also express this gene as well so it may have a role in different types of brain cancer. Among normal tissues derived from the central nervous system, the NOV1a gene is expressed in the amygdala, cerebellum, hippocampus and cerebral

Among tissues with metabolic function, the NOV1a gene is expressed in the pancreas and in adipose. Interestingly, this gene is also expressed at higher levels in fetal heart and skeletal tissue when compared to the adult tissues.

20

The NOV1a gene appears to be expressed at high levels in a sample from a renal cancer cell line and from a breast cancer cell line. In addition, the NOV1a gene is expressed in ovarian tissue, but not significantly in cell lines derived from ovarian cancer.

Panel 2D Sunmary <u>Ag708/Ag1313b</u> In two runs using two different probe and primer sets, highest expression of the NOV1A gene is seen in the normal ovary, colon und kidney. Furthermore, in all nine matched kidney pairs and in the matched tissue pair derived from the ovary, the NOV1A gene is expressed more highly in normal tissue than in the adjacent cancer samples. This result suggests that expression of the NOV1A gene could be used as a diagnostic marker for the presence of kidney and ovarian cancer. In addition, therapeutic upregulation of the gene activity of NOV1A could be effective in the treatment of kidney and ovarian cancer. The NOV1A gene is also expressed at higher levels in lung cancer samples, when compared to normal adjacent tissue in six out of seven matched lissue pairs. Thus, therapeutic inhibition of the NOV1a gene, through the application of antibodies or small

organs during inflammation. with this protein could be important for maintaining or restoring normal function to these could play an important role in the normal homeostasis of these tissues. Therapeutics designed and in a muco-cpidermoid cell line (11292). Thus, the protein encoded by the NOV1a gene highly in the thymus (CT 28.4). More moderate expression of this gene is observed in the lung discases-associated inflammation or neurodegeneration. The NOV a gene is also expressed astrocytes (CT 27.8) and its expression is down regulated upon treatment with TNF-a and IL-1b, suggesting that modulation of this protein could be beneficial in the treatment of CNS Panel 4D Summary Ag2197 The NOV1a gene is expressed at a high level in

S

>35) among the samples on this panel (data not shown). Fanel 4.1D Summary Ag4164 Expression of this gene is low/undetectable (CT values

low/undctcctable (CT values >35) among the samples on this panel (data not shown). Panel CNS\_neurodegeneration\_v1.0 Summary Ag4164 Expression of this gene is

2

5

4[AON

20

shown in Tables 22, 23, and 24. mismatch is not predicted to alter the RTQ-PCR results. Results from RTQ-PCR runs are Ag4164 contains a single mismalch in the probe relative to the NOV1b sequence. This the primer-probe sets Ag4164 and Ag2197 described in Tables 20 and 21. Please note that discussed independently below in section B. Expression of gene NOV1b was assessed using NOV to sequence only matches a subset of the probe and primer sets discussed above and is The NOV1b sequence is a variant of gene NOV1a annotated above. However, the

cell lines also express this gene as well so it may have a role in different types of brain cancer. Among normal tissues derived from the central nervous system, the NOV1a gene is expressed sample derived from a CNS cancer cell line (CT=27). Certain glioblastoma and astrocytoma Panel 1.3D Summary Ag2197 Highest expression of the NOV1a gene is seen in a in the amygdala, cerebellum, hippocampus and cerebral cortex.

Ś

Among tissues with metabolic function, the NOV1a gene is expressed in the pancreas and in adipose. Interestingly, this gene is also expressed at higher levels in fetal heart and skeletal tissue when compared to the adult tissues.

2

cancer cell line and from a breast cancer cell line. In addition, the NOV1a gene is expressed in The NOV1a gene appears to be expressed at high levels in a sample from a renal ovarian tissue, but not significantly in cell lines derived from ovarian cancer.

2

colon tissue (CT=25). The gene is also expressed at high levels in the uterus, but not in uterine could potentially be useful in the treatment of uterine cancer. The NOV1b gene also appears to be expressed at higher levels in liver cancers (two out of two matched tissue pairs) and kidney cancers (seven out nine matched lissue pairs) when compared to normal adjacent lissue. Thus, cancer. Thus, expression of NOV1b could be used as a diagnostic marker for the presence of uterine cancer. Furthermore, therapeutic upregulation of the activity of the protein product Panel 2D Summary Ag2197 Expression of the NOV1b gene is highest in normal

2

expression of the NOV1b gene could be used to diffentiate between kidney and liver cancers and other cancers or normal tissue. Furthermore, thereapeutio inhibition of the activity of the protein encoded by the NOV1b gene, through the use of antibodies or small molecule drugs, could be effective in treating kidney and liver cancers.

highly in the thymus (C1 28.4). More moderate expression of this gene is observed in the lung could play an important role in the normal homeostasis of these tissues. Therapeutics designed astrocytes (CT 27.8) and its expression is down regulated upon treatment with TNF-a and ILdiseases-associated inflammation or neurodegeneration. The NOV1a gene is also expressed and in a muco-epidermoid cell line (H292). Thus, the protein encoded by the NOV la gene lb, suggesting that modulation of this protein could be beneficial in the treatment of CNS with this protein could be important for maintaining or restoring normal function to these Panel 4D Summary Av2197 The NOV1a gene is expressed at a high level in organs during inflammation. 2

Panel 4.1D Summary Ag4164 Expression of this gene is low/undetectable (CT values >35) among the samples on this panel (data not shown).

2

Panel CNS\_neurodegeneration\_v1.0 Summary Ag4164 Expression of this gene is low/undetectable (CT values >35) among the samples on this panel (data not shown).

2

NOVIc

22

Please note that the NOV1c sequence is a variant of gene NOV1a annotated in section NOV1c was assessed using the primer-probe sets Ag2197, Ag708 and Ag1313b described in Tables 25, 26, and 27. Results from RTQ-PCR runs are shown in Tables 28, 29, 30, and 31. discussed above and is discussed independently below in section C. Expression of gene A. However, the NOV1c sequence only matches a subset of the probe and primer sets

Panel 1.2 Summary Ag708 Expression of the NOV1a gene was assessed in two independent experiments using the same probe/primer set. There appears to be poor concordance between runs for some tissues but there is good concordance for others; only those results that are in agreement will be discussed here. In both experiments, highest expression of the NOV1a gene in a sample derived from a glioblastoma cell line (CTs = 24-26). Among normal tissues derived from the central nervous system, the NOV1a gene is also expressed at moderate levels in the cerebral cortex, cerebellum and hippocampus.

Among tissues with metabolic function, the NOV1a gene is expressed in the pancreas. Thus, this gene may be involved in the pathogenesis and/or treatment of diseases involving the pancreas, such as pancreatitis and diabetes. In addition, NOV1a gene expression is decreased in a pancreatic cancer cell line.

5

The NOV1a gene appears to be overexpressed in fetal kidney when compared to the adult kidney. This result suggests that the NOV1a gene could be used to distinguish between adult and fetal kidney tissue and that this gene may play an important role in kidney development, growth and survival. Furthermore, NOV1a gene expression is higher in normal ovary, mammary gland and lung when compared to the cancer cell lines obtained from these tissues suggesting that this can be used as a marker to differentiate malignant and normal tissue.

Panel 1.3D Summary <u>Ag708/ Ag1313b/Ag2197</u> Three experiments with three different probe and primer sels produced results that were in very good agreement. One run, designated 1.3dx4tm5365t, appears to have lower absolute expression, but produces the same expression profile as the other two experiments. Highest expression of the NOV1a gene in all three runs is seen in a sample derived from a CNS cancer cell line (CTs=27). Certain glioblastoma and astrocytoma cell lines also express this gene as well so it may have a role in different types of brain cancer. Annong nonnal tissues derived from the central nervous

system, the NOV1a gene is expressed in the amygdala, cerebellum, hippocampus and cerebral

Among tissues with metabolic function, the NOV1a gene is expressed in the pancreas and in adipose. Interestingly, this gene is also expressed at higher levels in fetal heart and skeletal tissue when compared to the adult tissues.

Ś

2

The NOV1 a gene appears to be expressed at high levels in a sample from a renal cancer cell line and from a breast cancer cell line. In addition, the NOV1 a gene is expressed in ovarian tissue, but not significantly in cell lines derived from ovarian cancer.

Panel 2D Summary Ag708/Ag1313b/Ag2197 In two runs using two different probe and primer sets, highest expression of the NOV1a gene is seen in the normal ovary, colon and kidney. Furthermore, in all nine matched kidney pairs and in the matched tissue pair derived from the ovary, the NOV1a gene is expressed more highly in normal tissue than in the adjacent cancer samples. This result suggests that expression of the NOV1a gene could be used as a diagnostic marker for the presence of kidney and ovarian cancer. In addition, thempeutic upregulation of the gene activity of NOV1a could be effective in the treatment of kidney and ovarian cancer. The NOV1a gene is also expressed at higher levels in lung cancer samples, when compared to normal adjacent tissue in six out of seven matched tissue pairs. Thus, therapeutic inhibition of the NOV1a gene, through the application of antibodies or small molecule drugs, could be effective in the treatment of lung cancer.

2

20

Panel 4D Summary Ag2197 The NOV1a gene is expressed at a high level in astrocytes (CT 27.8) and its expression is down regulated upon treatment with TNF-a and IL-1b, suggesting that modulation of this protein could be beneficial in the treatment of CNS diseases-associated inflammation or neurodegeneration. The NOV1a gene is also expressed highly in the thymus (CT 28.4). More moderate expression of this gene is observed in the lung and in a muco-epidermoid cell line (H292). Thus, the protein encoded by the NOV1a gene could play an important role in the normal homeostasis of these tissues. Therapeutics designed with this protein could be important for maintaining or restoring normal function to these organs during inflammation.

25

NOV3

2

229

Expression of gene NOV3 was assessed using the primer-probe set Ag1534 described in Table 32. Results from RTQ-PCR runs are shown in Tables 33, 34, 35, and 36.

Table 32. Probe Name Ag1534

Panel 1.2 Summary Ag1534 The NOV3 gene encodes a protein with homology to the iteal sodium/bile cotransporter. Highest expression of this gene is detected in the kidney (CT=28.1). The NOV3 gene appears to be expressed in clusters of cell lines derived from breast cancer, ovarian cancer, lung cancer, renal cancer and melanoma. Thus expression of this gene could be used to detect the presence of any of these cancers. Furthermore, therapeutic modulation of the expression of the NOV3 gene or the activity of its protein product may be beneficial in the treatment of breast cancer, ovarian cancer, lung cancer, renal cancer and

S

Among tissues involved in metabolic function, the NOV3 gene is expressed in the thyroid, adrenal gland, heart, liver, and skeletal nuscle. Thus, the protein encoded by the NOV3 gene could be involved in the pathogenesis and/or treatment of diseases that involve any of these tissues. Furthermore, the NOV3 gene is expressed at higher levels in adult heart issue (CT=29.7) than in fetal heart lissue (CT=33.6). Therefore, expression of the NOV3 gene could also be used to differentiate between adult and fetal heart tissue.

~

melanoma.

2

The NOV3 gene is also widely expressed in tissues originating in the central nervous system. These tissues include the fetal brain, amygdala, hippocampus, thalamus, cerebral cortex and spinal cord. This transporter gene most likely plays a role in the uptake of nutrients. Blockade of this transporter may decrease the loss of neurons due to excitotoxicity during ischemic stroke.

ន

Panel 1.3D Summary <u>Ag1534</u> Highest expression of the NOV3 gene in Panel 1.3D is detected in the hippocampus (CT=31.2). This gene is also expressed in the amygdala and cerebral cortex. Please see Panel 1.2 summary for discussion of potential utility of this gene with respect to CNS function.

55

Among tissues with metabolic function, the NOV3 gene is expressed in the thyroid, pituitary gland, adipose, and fetal skeletal muscle. Interestingly, this gene is much more highly expressed in fetal skeletal muscle (CT=33.4) than in adult skeletal muscle (CT=40), suggesting that this gene could be used to distinguish the two. In addition, the increased NOV3

ဓ္က

gene expression in fetal skeletal muscle when compared to adult suggests that the protein product may enhance muscular growth or development in the fetus and thus may also act in a regenerative capacity in the adult. Therefore, therapeutic modulation of the NOV3 gene could be useful in treatment of muscular related disease. More specifically, treatment of weak or dystrophic muscle with the protein encoded by this gene could restore muscle mass or function. This gene is also more highly expressed in fetal kidney, lung and brain when compared to the corresponding adult tissues.

Panel 2D Summary Ag1534 The NOV3 gene is most highly expressed in a kidney to cancer (CT=31.1). In general, however, this gene is more commonly expressed at higher levels in normal tissues than the adjacent tumor tissues. Specifically, this gene is expressed at higher levels in normal adjacent tissues next to thyroid cancer as well as adjacent to some kidney and lung cancers. These data indicate that NOV3 gene expression might be used to distinguish normal tissue from malignant tissue and also that therapeutic modulation of this gene product might be of use in the treatment of these types of cancer.

Panel 3D Summary <u>Ag 1534</u> Highest expression of the NOV3 gene is detected in a cell line derived from a medulloblastoma (CT=30.1). Additionally there is expression in a obnonic myelogenous leukemia (megokaryoblast) cell line, a gastric adenocarcinoma cell line, a clear cell renal carcinoma cell line, a pancreatic ductal adenocarcinoma cell line and a small cell lung cancer cell line. Thus, the expression of this gene could be used to distinguish some cancer cell lines from others. In addition, these data indicate that the expression of the NOV3 gene might be associated with these forms of cancer and thus, therapeutic modulation of this gene might be of use in the treatment of cancer.

 Oelkers P, Kirby LC, Heubi JE, Dawson PA. Primary bile acid malabsorption caused by mutations in the ileal sodium-dependent bile acid transporter gene (SLC10A2). J Clin Invest 1997 Apr 15;99(8):1880-7.

2

Primary bite acid malabsorption (PBAM) is an idiopathic intestinal disorder associated with congenital diarrhea, steatorthea, interruption of the enterohepatic circulation of bile acids, and reduced plasma cholesterol levels. The molecular basis of PBAM is unknown, and several conflicting mechanisms have been postulated. In this study, we cloned the human ileal

Na+/bile acid cotransporter gene (SLC10A2) and employed single-stranded conformation

polymorphism analysis to screen for PBAM-associated mutations. Four polymorphisms were identified and sequenced in a family with congenital PBAM. One allele encoded an A171S missense mutation and a mutated donor splice site for exon 3. The other allele encoded two missense mutations at conserved amino acid positions, L243P and T262M. In transfected COS cells, the L243P, T262M, and double mutant (L243P/T262M) did not affect transporter protein expression or trafficking to the plasma membrane; however, transport of taurocholate and other bile acids was abolished. In contrast, the A171S mutation had no effect on taurocholate uptake. The dysfunctional mutations were not detected in 104 unaffected control subjects, whereas the A171S was present in 28% of that population. These findings establish that SUC10A2 mutations can cause PBAM and underscore the iteal Na+/bile acid colransporter's role in intestinal reclamation of bile acids.

#### NOV4

ᅜ

5

Expression of gene NOV4 was assessed using the primer-probe sets Ag2432 and Ag1250 described in Tables 37 and 38. Results from RTQ-PCR runs are shown in Tables 39, 40, 41, and 42.

Panel 1.2 Summary Ag1250 The NOV4 gene is expressed at high levels in lung cancer cell lines. Overall, there is a predominant expression pattern that shows higher expression of this gene in cancer cell lines when compared to normal tissues. Specifically, the NOV4 gene is expressed at higher levels in samples derived from colon cancer, ovarian cancer, presst cancer and melanoma cell lines. Thus, expression of the NOV4 gene could be used to distinguish cultured cell lines from normal tissues. In addition, these data indicate that the expression of this gene might be associated with these forms of cancer and thus, therapeutic modulation of the NOV4 gene product might be of use in the treatment of these cancers.

Panel 1.3D Summary <u>Ag2432</u> Expression of the NOV4 gene is limited to the hippocampus (CT=27.6), where it is expressed at high levels. Therefore, expression of this gene could be used to distinguish hippocampus from other tissues.

2

Panel 2D Summary <u>Av2432</u> Significant but low expression of the NOV4 gene is detected in normal colon and bladder tissues. Therefore, expression of this gene could be used to distinguish colon and bladder from other tissues.

Panel 4D Suramary <u>Ag1250</u> The NOV4 gene encodes a protein with homology to prohibitins, which are proteins that have been shown to be involved various functions, including cell cycle regulation, apoptosis, assembly of mitochondrial respiratory chain

ଧ

enzymes, and aging (ref. 1). The NOV4 gene is expressed at moderate levels throughout the samples on this panel (CTs=30.8-33.6). Interestingly, however, this gene is expressed at highest levels in the thymus as well as in activated Th1 and Th2 T cells. Given this expression pattern, the NOV4 gene product may play an important role in the normal homeostasis of the thymus and might be associated with the activation process of T cells. Therefore, modulation of this protein by small molecule drugs might be important for controlling T cell activation and could have some benefit for treatment of diseases associated with hyperactive T cells, such as autoimmune disease, delayed type hypersentivity, and other T cell mediated diseases (such as asthma and psoriasis). In addition, the NOV4 gene is also expressed in activated B cells and in a Ramos B cell line. It has been suggested that increased prohibitin expression is associated with and may facilitate B-cell maturation (ref. 2). Thus, modulation of this protein by small molecule drugs might be important for controlling B differentiation and the generation of immunoglobulins by B cells and could therefore have some therapeutic benefit in the treatment of hypoglobulinemia.

5

Panel CNS\_neurodegeneration\_v1.0 Summary <u>Ag2432</u> Expression of this gene is low/undetectable (CT values >35) among the samples on this panel (data not shown).

 Coates PJ, Nenutil R, McGregor A, Picksley SM, Crouch DH, Hall PA, Wright EG. Mammalian prohibitin proteins respond to mitochondrial stress and decrease during cellular senescence. Exp Cell Res 2001 May 1;265(2):262-73

25

The two prohibitin proteins, Phb1p and Phb2p(BAP37), have been ascribed various functions, including cell cycle regulation, apoptosis, assembly of mitochondrial respiratory chain enzymes, and aging. We show that the mammalian prohibitins are present in the inner mitochondrial membrane and are always bound to each other, with no free protein detectable. They are coexpressed during development and in adult mammalian tissues, and expression levels are indicative of a role in mitochondrial metabolism, but are not compatible with roles in the regulation of cellular proliferation or apoptosis. High level expression of the proteins is consistently seen in primary human tumors, while cellular senescence of human and chick fibroblasts is accompanied by heterogeneous decreases in both proteins. The two proteins are induced by metabolic stress caused by an imbalance in the synthesis of mitochondrial- and nuclear-encoded mitochondrial proteins, but do not respond to oxidative stress, heat shock, or

30

35

other cellular stresses. The gene promoter sequences contain binding sites for the Myc oncoprotein and overexpression of Myc induces expression of the prohibitins. The data support conserved roles for the prohibitins in regulating mitochondrial respiratory activity and in aging.

25 20 2 expression of a 30-kDa heat shock protein 60 (hsp60) analog. During our efforts to further with and may facilitate B-cell maturation. B-lymphocyte populations. An antisense oligonucleotide complementary to the 5' coding malured compared to resting CLL B-cells as determined by quantitative Western immunoblot proliferation and inhibits cell cycle traverse in several systems, although few data are available prohibitin in phorbol-ester-matured CLL B-lymphocytes. Prohibitin modulates cell characterize this hsp60 analog by mass spectrometry, we detected the mitochondrial protein expression of specific plasma membrane and mitochondrial proteins including heightened treated in vitro with phorbol esters. CLL B-cell apparent maturation is associated with altered immature B-lymphocytes. CLL B-lymphocytes mature to a plasmacytoid phenotype when analysis. A similar increase in prohibitin was observed in phorbol-ester-treated normal human for lymphocytes. A twofold increase in prohibitin concentration wasobserved in phorbol-ester CLL B-cells by 42%. These data suggest that increased prohibitin expression is associated region of the prohibitin gene blunted the increase in prohibitin protein in phorbol-ester-treated Chronic lymphocytic leukemia (CLL) is characterized by the gradual accumulation of

Met, the receptor for HGF, is expressed in developing rat hippocampus, with the highest levels prepared from embryonic rats and treated with different HGF concentrations. In these cultures, the degree of sprouting of calbindin D-positive neurons, suggesting an influence on neuronal maturation. BDNF and NT-3 stimulated neurite outgrowth of calbindin D neurons to a much (calbindin D) in u dose-dependent manner. The effect of HGF was larger than that observed calbindin D neurons. Besides affecting the number of neurons, HGF significantly increased nervous system, and has been shown to exhibit neurotrophic activity. Here we show that cduring the first postnatal weeks. To study the function of HGF, hippocampal neurons were calbindin D- and HGF-immunoreactive cells are all present in the dentate gyrus and partly hippocampal neurons and increases their neurite outgrowth, suggesting that HGF plays an Hepatocyte growth factor-scatter factor (HGF) is expressed in different parts of the smaller degree. In contrast to calbindin D neurons, HGF did not significantly increase the number of neurons immunoreactive with the neurotransmitter gamma-aminobutyric acid (GABA) in the hippocampal cultures. Innnunohistochemical studies showed that o-Met-, cotreatment of the cultures with HGF and the neurotrophins was additive with respect to colocalize within neurons. These results show that HGF acts on calbindin D-containing HGF increased the number of neurons expressing the 28-kDa calcium-binding protein with either brain-derived neurotrophic suctor (BDNF) or neurotrophin-3 (NT-3), and important role for the maturation and function of these neurons in the hippocampus.

Cortical interneurons arise from the proliferative zone of the ventral telencephalon, the addition, exogenous ligand disrupts normal cell migration. Mice lacking the urokinase-type forebruin explants demonstrate regionally specific motogenic activity due to HGF/SF. In plasminogen activator receptor (u-PAR), a kcy component of HGF/SF activation, exhibit ganglionic entinence, and migrate into the developing neocortex. The spatial patterns of factor/scatter factor (HGF/SF) and its receptor, MET, in the forebrain. Scatter assays on migratory interneurons reflect the complementary expression of hepatocyte growth

35

deficient scatter activity in the forebrain, abnormal interneuron migration from the ganglionic eninence, and reduced intemeurons in the frontal and parietal cortex. The data suggest that HGF/SF motogenic activity, which is essential for normal development of other organ systems, is a conserved mechanism that regulates trans-telencephalic migration of interneurons.

Macrophage stinulating protein (MSP), also known as hepatocyte growth factor-like, receptors. MSP was originally isolated as a chemotactic factor for peritoneal macrophages. is a soluble cytokine that belongs to the family of the plasminogen-related growth factors (PRGFs). PRGFs are alpha/beta heterodimers that bind to transmembrane tyrosine kinase Through binding to its receptor, encoded by the RON gene, it stimulates dissociation of 2

(NO). Here, we identify a novel role for MSP in the central nervous system. As a paradigm to analyze this function we chose the hypoglossal system of adult mice. We demonstrate in vivo that either administration of exogenous MSP or transplantation of MSP-producing cells at the epithelia and works as an inflammatory mediator by repressing the production of nitric oxide proximal stump of the resected nerve is sufficient to prevent motoneuron atrophy upon 2 2

notoneurons and, by regulating the production of NO, may have a role in brain plasticity and typoglossal nerve, and that MSP induces biosynthesis of Ron receptor in the motoneuron somata. Finally, we show that MSP suppresses NO production in the injured hypoglossal nuclei. Together, these data suggest that MSP is a novel neurotrophic factor for cranial axotomy. We also show that the MSP gene is expressed in the tongue, the target of the

developing and adult mammalian brain. Recent studies have shown a neurotrophic activity of HGF in the nervous system. The present study focused on HGF concentrations in the depalocyte growth factor (HGF) and its specific receptor, MET, are expressed in the

cerebrospinal fluid (CSF) and serum in normal persons and in different central nervous system 35

(CNS) diseases considering blood-CSF barrier (BCB) function. Concentrations of HGF were analyzed using an enzyme-linked immunosorbent assay (ELISA). HGF was present in normal human CSF (346+/-126 pg/ml) representing approximately half of the HGF serum concentrations. The CSF HGF levels were not significantly changed in chronic CNS disease and in aseptic meningilis (419+/-71 pg/ml), but significantly increased in patients with bacterial meningitis (6101+/- 5200 pg/ml). The HGF levels in CSF were not influenced by increased serum concentrations in patients with normal or mildly affected BCB function. The results show that HGF is present in normal CSF and does not appear to cross the CSF barrier significantly unless it is severely disrupted. So far, strong increases of HGF concentration in CSF are only present in acute bacterial meningilis. Copyright 2001 Academic Press.

To develop a novel strategy to prevent delayed neuronal death (DND) following transient occlusion of arteries, the gene of hepatocyte growth factor (HGF), a novel neurotrophic factor was transfected into the subarachnoid space of gerbils after transient forebrain ischemia. Importantly, transfection of HGF gene into the subarachnoid space prevented DND, accompanied by a significant increase in HGF in the cerebrospinal fluid. Prevention of DND by HGF is due to the inhibition of apoptosis through the blockade of bax translocation from the cytoplasm to the nucleus. HGF gene transfer into the subarachnoid space may provide a new therapeutic strategy for cerebrovascular disease.

The c-Met oncoprotein is a cell-surface receptor for hepatocyte growth factor (HGF). Signals through HGF and c-Met have been appreciated for their crucial roles in the development of many cell types, including liver cells. The present study examined whether o-Met is expressed in the thymus and whether c-Met/HGF signals can regulate T-cell development in the thymus. We have found that mRNA transcripts encoding c-Met are expressed in mouse thymus. The c-Mct transcripts were expressed at higher levels in fetal and 263

35

neonatal thymus than in adult thymus, and were mostly expressed by lymphoid cells rather than by stromal cells. Interestingly, the addition of HGF to fetal thymus organ cultures increased the generation of mature T cells expressing high levels of T-cell antigen receptors. These results indicate that c-Met is expressed in the thymus during early ontogeny, and that c-Met/HGF signals can promote T-cell development:

Panel 1.3D Summary Ag2432 The NOV6 gene is widely expressed across the samples in this panel, with highest expression detected in the hippocampus (CT=28.1). This gene is also expressed at lower levels in the other tissues originating from the central nervous system, including the amygdala, corebellum, cerebral cortex, substantia nigra, thalamus, and spinal cord. Thus, NOV6 gene expression may be used to distinguish hippocampus from other tissues. Please see CNS\_neurodegeneration\_panel\_v1.0 summary for a discussion of the potential utility of this gene in CNS disorders.

Among tissues involved in metabolic function, the NOV6 gene is also expressed in thyroid, adrenal gland, pituitary gland, pancreas, heart (adult and fetal), liver (adult and fetal), and adipose. Interestingly, this gene is more highly expressed in fetal skeletal muscle (CT = 29.4) than in adult skeletal muscle (CT = 33.4). This observation suggests that the NOV6 protoin product may enhance muscular growth or development in the fetus and thus may also act in a regeneralive capacity in the adult. Therefore, therapeutic modulation of the NOV6 gene could be useful in treatment of muscular related disease. More specifically, treatment of weak or dystrophic muscle with the protein encoded by this gene could restore muscle mass or function.

2

ᅜ

5

The NOV6 gene is also expressed at higher levels in gastric, colon, melanoma, lung, and colon cancer cell lines than in normal tissues. Therefore, this gene may be used as a marker for gastric cancer, colon cancer, melanoma, lung, and colon cancer cell lines. In addition, therapeutic modulation of the NOV6 gene product might be of use in the treatment of these cancers.

20

Panel 2D Summary Ag2439 The NOV6 gene is most highly expressed in a sample derived from normal colon (CT=26). However, in general this gene appears to be more highly expressed in cancers than in normal tissues. Specifically, NOV6 gene expression is slightly higher in lung cancer (squamous cell type), gastric cancer, ovarian cancer, a kidney cancer sample and a sample of breast cancer relative to the normal controls. Thus, the expression of this gene could be used to distinguish malignant colon, lung, stomach, ovary and some breast and kidney tissue from normal tissue from these organs. In addition, therapeutic modulation of the NOV6 gene product might be of use in the treatment of these cancers.

25

೪

Panel 4D Summary <u>Ag2439</u> The NOV6 gene is most highly expressed in ionomycintreated Ramos B cells (CT = 26). This gene is also expressed at moderate levels in T cells, monocytes, dendritic cells, endothelial cells, smooth muscle cells, and airway epithelial cells both under resting and cytokine-stimulated conditions. Therefore, this gene may be useful as a marker for these resting and activated cells.

Panel CNS\_neurodegeneration\_v1.0 Summary Ag2439 The NOV6 gene encodes a protein with homology to fatty acid binding protein and is expressed across the brain, although expression appears to be the highest in the hippocampus (Panel 1.3D). This gene does not appear to be differentially expressed in Alzheimer's disease based on the results from panel CNS\_Neurodegeneration\_V1.0, although the transcript is detected at low levels in many of the brain samples. Fatty acid binding protein expression is increased in development during axon growth and during the response to injury, probably for the transport of fatty acids for use as membrane components (ref. 1). Therefore, upregulation of the NOV6 gene or its protein product may be beneficial during neurite outgrowth and synaplogenesis in response to neuronal death or injury (Parkinson's disease, Alzheimer's disease, Huntington's disease, spinocerebellar ataxia, stroke, and head/spinal cord trauma).

 Liu Y, Molina CA, Welcher AA, Longo LD, De Leon M. Expression of DA11, a neuronalinjury-induced fatty acid binding protein, coincides with axon growth and neuronal differentiation during central nervous system development. J Neurosci Res 1997 Jun 15;48(6):551-62.

z

DA11 is the first fally acid binding protein (FABP) for which gene expression has been shown to be upregulated following neuronal injury in the adult peripheral nervous system. To understand better the potential regulatory role(s) of this unique FABP in axonal growth and neuronal differentiation, we underdook a temporal and spatial study of DA11 gene expression in the developing rat central nervous system (CNS). Transient upregulation of DA11 mRNA and protein levels in CNS tissues were quantified by Northern blot hybridization and Western immunoblot analyses at different developmental ages. Homogenates of embryonic and neonatal cerebral cortex, cerebellum, brain stem, and hippocampal tissues contained 100-fold more DA11 mRNA and protein than corresponding adult tissues. Significant increase in DA11 mRNA was observed as early as embryonic day (E) 14 in cerebral cortex and cerebellum and 272

and intracellular compartments at P9 revealed a spatial pattern of neuronal expression different with development throughout the CNS suggests that this unique FABP plays an important role brain stem, spinal cord, and olfactory bulb. The strong association of DA11 gene expression cerebellum. Localization of DA11-like immunoreactivity to specific CNS tissues, cell types, axons, and dendrites of differentiating neurons in cerebral cortex, hippocampus, cerebellum, than that reported for other FABPs. DA11 protein was detected in the nucleus, cytoplasm, E19 in brain stem and hippocampus. Postnatal levels of DA11 remained elevated through postnatal day (P) 10 in cerebral cortex, P14 in brain stem and hippocampus, and P20 in in axonal growth and neuronal differentiation in many different neuronal populations.

Panel 1.3D Summary <u>Ag2771</u> Expression of the NOV9 gene is highest in normal bladder (CT=27.2). This gene is more highly expressed in colon cancer cell lines relative to normal colon as well as in some lung cancer cell lines relative to normal lung. Thus, expression of this gene could be used to distinguish between colon or lung cancer cell lines and other cell lines. Furthermore, therapeutic inhibition of the NOV9 gene or its protein product, throught the use of antibodics, small molecule or protein drugs, may be effective in the treatment of colon and lung cancers.

S

5

The NOV9 gene is expressed at moderate levels throughout CNS, with expression detected in fetal brain, amygdala, cerebellum, hippocampus, substantia nigra, thalamus,

cerebral cortex and spinal cord (CTs=29-33). See CNS\_neurodegeneration\_panel\_v1.0 summary for potential utility of this gene in CNS disorders.

Among tissues with metabolic function, this gene shows low expression in pancroas, adrenal gland, pituitary gland, and liver (adult and fetal) with higher expression in thyroid, heart (adult and fetal), skeletal muscle (adult and fetal), and adipose. Therefore, the NOV9 gene product may play a role in the pathogenesis and/or treatment of metabolic diseases in any or all of these tissues, including obesity and diabetes.

Panel 2D Summary Ag2771 Highest expression of the NOV9 gene is found in a kidney cancer sample (CT=23). However, lluis gene is rather ubiquitously expressed at moderate levels in all the tissue samples on this panel. Interestingly, the level of NOV9 gene expression appears to be lower in liver and lung tissues when compared to other organs. In addition, this gene appears to be overexpressed in ovarian cancers as well as in several colon cancers relative to the normal controls. The expression patterns suggest that this gene is required for the survival and proliferation of the majority of cell types.

5

2

CDC-42-interacting protein 4 and is highly expressed in resting HUVEC endothelial cells (CT=24-25), lung microvascular endothelium, bronchial epithelium, small airway epithelium, coronary artery smooth muscle cells, as well as in mucoepidermoid cells (NCI-H292). Basal expression of this gene in these cells appears to be decreased by various treatments with proinflammatory cytokines, such as IL-1beta, IL-4, IL-11, IFN-gamma, and TNF-alpha. CDC-42-interacting protein 4 is a Cdc42 effector protein involved in cytoskeletal organization (ref. 1-2). Since cytokine-activated cells express lower levels of the NOV9 gene, increasing the activity of this gene product may reduce the pro-inflammatory effects of these cytokines. Therefore, the NOV9 gene product may be a useful target for agonistic small molecule therapeutics that increase activity of the protein, and such small molecule drugs may reduce the severity of symptoms of asthma and inflammatory bowel disease.

30 Panel CNS\_neurodegeneration\_v1.0 Summary Ag2771 CDC42 has been implicated as a neuronal death effector in Alzheimer's disease and as playing an essential role in cerebellar granule neuron survival (refs. 4-6). Cdc42-interacting protein 4, which is homologous to the NOV9 gene, has been identified as a substrate of CDC42 (ref. 2).

Therefore, drugs that inhibit NOV9 gene product activity may be effective in blocking processes downstream of CDC42, such as neuronal death in Alzheimer's disease. Since

CDC42 can mediate both desirable (cerebellar neuronal survival) and undesirable

(Alzheimer's disease) processes, it is likely that specifically targeting distinct downstream substrates may enable the effective targeting of distinct processes without affecting other

CDC42-mediated processes. The NOV9 gene is expressed in the human brain in all regions examined, including the cerebral cortex, hippocampus, annygdala, cerebellum, substantia

Š

nigra, spinal cord and thalanus (see Panel 1.3D). Additionally, this gene is expressed more highly in the hippocampus of some patients with Alzheimer's disease than in normal control brains, indicating a possible pathological role in neurodegenerative brain disease. Therefore,

targeting the NOV9 gene product may have utility in selective targeting of undesirable CDC42-medialed processes, such as Alzheimer's disease.

2

Podosomes are unique actin-rich adhesion structures of monocyte-derived cells such as macrophages and osteoclasts. They clearly differ from other substratum-contacting organelles like focal adhesions in morphological and functional regards. Formation of podosomes has been shown to be dependent on the small GTPase CDC42Hs and its effector Wiskott-Aldrich syndrome protein (WASp). In this study, we investigated the functional relation between podosomes and the microtubule system in primary human macrophages. We demonstrate that, in contrast to focal adhesions, assembly of podosomes in macrophages and their monocytic precursors is dependent on an intact microtubule system. In contrast, experiments using

20

Wiskott-Aldrich syndrome (WAS) macrophages indicate that the microtubule system is not reciprocally dependent on podosomes. A potential linker between podosomes and microtubules may be WASp itself, considering that microinjection of the WASp polyproline domain prevents podosome reassembly. This polyproline domain is thought to link WASp to microtubules via CDC42 interacting protein 4 (CIP4). Consistently, macrophages microtubules via CDC42 interacting protein and there the microtubule- or the WASp-binding domain also fail to reassemble podosomes. In sum, our findings show that microtubules are essential for podosome formation in primary human macrophages and that WASp and CIP4 may be involved in this phenomenon.

 Tian L, Nelson DL, Stewart DM. Cdc42-interacting protein 4 mediates binding of the Wiskott-Aldrich syndrome protein to microtubules. J Biol Chem 2000 Mar 17;275(11):7854-

5 61

The Wiskott-Aldrich syndrome is an inherited X-linked inmunodeficiency characterized by thrombocytopenia, eczema, and a tendency toward lymphoid malignancy. Lymphocytes from affected individuals have cytoskeletal abnormialities, and monocytes show impaired motility.

10 The Wiskott-Aldrich syndrome protein (WASP) is a multi-domain protein involved in cytoskeletal organization. In a two-hybrid screen, we identified the protein Cdc42-interacting protein 4 (CP4) as a WASP interactor. CP4, like WASP, is a Cdc42 effector protein involved in cytoskeletal organization. We found that the WASP-CP4 interaction is mediated by the binding of the Src homology 3 domain of CIP4 to the proline-rich segment of WASP. Cdc42

WASP in COS-7 cells led to the association of WASP with microtubules. In vitro experiments showed that CIP4 binds to microtubules via its NH(2) terminus. The region of CIP4 responsible for binding to active Cdc42 was localized to amino acids 383-417, and the mutation I398S abrogated binding. Deletion of the Cdc42-binding domain of CIP4 did not

20 affect the colocalization of WASP with microtubules in vivo. We conclude that CIP4 can mediate the association of WASP with microtubules. This may facilitate transport of WASP to sites of substrate adhesion in hematopoietic cells.

 Aspenstrom P.A Cdc42 target protein with homology to the non-kinase domain of FER has a potential role in regulating the actin cytoskeleton. Curr Biol 1997 Jul 1;7(7):479-87 BACKGROUND: Members of the Rho family of small GTPases have been shown to have a diverse role in cell signalling events. They were originally identified as proteins that, by

diverse role in cell signalling events. They were originally identified as proteins that, by regulating the assembly of the actin cytoskeleton, are important determinants of cell morphology, and have recently been shown to be involved in transcriptional activation by the JNK/SAPK signalling pathway. In order to understand the mechanisms underlying the effects of Rho GTPases on these processes, the yeast two-hybrid system has been used to identify

proteins that bind to an activated mutant of Cdc42, a Rho-family member. RESULTS: A cDNA encoding a previously unidentified Cdc42 target protein, CIP4, which is 545 amino-acids long and contains an SH3 domain at its carboxyl terminus, was cloned from a human B-cell library. The amino terminus of CIP4 bears resemblance to the non-kinase domain of the FER and Fes/Fps family of tyrosine kinases. In addition, similarities to a number of proteins with roles in regulating the actin cytoskeleton were noticed. CIP4 binds to activated Cdc42 in vitro and in vivo and overexpression of CIP4 in Swiss 3T3 fibroblasts reduces the amount of stress fibres in these cells. Moreover, coexpression of activated Cdc42 and CIP4 leads to clustering of CIP4 to a large number of foci at the dorsal side of the cells. CONCLUSIONS: CIP4 is a downstream target of activated GTP-bound Cdc42, and is similar in sequence to proteins involved in signalling and cytoskeletal control. Together, these findings suggest that CIP4 may act as a link between Cdc42 signalling and regulation of the actin cytoskeleton.

Zhu X, Raina AK, Boux H, Simmons ZL, Takeda A, Smith MA.
 Activation of oncogenic pathways in degenerating neurons in Alzheimer disease. Int J Dev Neurosci 2000 Jul-Aug; 18(4-5):433-7

A number of recent findings have highlighted the similarities between neurogenesis during

considerable overlap with early cytoskeletal abnormalities suggesting that these changes are an contributes to neuronal degeneration. In fact, these findings suggest that Alzheimer disease is Cdc42/Rac in various cellular processes known to be perturbed in Alzheimer disease, namely development and neurodegeneration during Alzheimer disease. In fact, neuronal populations that are known to degenerate in Alzheimer disease exhibit phenotypic changes characteristic investigating components of the cell cycle, known to trigger progression through G1 through activation of signal transduction cascades. Specifically, we found that proteins implicated in G1 transition, namely Cdc42/Rac, are upregulated in select neuronal populations in cases of increased neuronal Cdc42/Rac is highly significant in relation to the pathogenic process and Alzheimer disease in comparison to age-matched controls. Importantly, Cdc42/Rac shows extremely proximal event in the pathogenesis of the disease. Given the functional role of of cells re-entering the cell division cycle. In this study, we extended these findings by cytoskeletal organization, oxidative balance, and oncogenic signaling, it is likely that an oncogenic process.

BA4, BA9 and cingulate gyrus region of a Parkinson's disease brain than in the control brains. In addition, expression of this gene is 5-fold higher in the substantia nigra and cingulate gyrus suggests that overexpression of the NOV10a gene in these regions is particular to Parkinson's disease. The substantia nigra is particularly vulnerable in Parkinson's disease, indicating that proteases. This gene is more highly expressed in the substantia nigra, globus palladus, BA17, The NOV10a gene encodes a protein with homology to hepsin/plasma transmembrane serine of a Parkinson's disease brain than in similar regions from the brains of patients with other neurodegenerative diseases, such as Alzheinner's or Huntington's disease; this observation Panel CNS\_1/CNS\_1.1/Panel CNS\_neurodegeneration\_v1.0 Summary Ag1674

the NOV10a gene product may be a component of the biological dysregulation that contributes

2

to Parkinson's disease pathogenesis. In particular, the NOV10a gene may be involved in the

neuronal death that occurs in the substantia nigra in Parkinson's disease.

2

of other diseases in addition to Parkinson's disease, such as Alzheimer's disease. Based on the control brains. This observation suggests that this gene may play a role the neurodegeneration The NOV10a gene is also more highly expressed in the superior/inferior temporal cortex, globus palladus, and hippocampus of an Alzheimer's brain when compared to the proposed role of transmembrane proteuses such as beta secretase in neurodegenerative

disorders, agents that influence the activity of the NOV10a gene product may be useful in treating these disorders, especially Parkinson's disease in which this gene appears to be dramatically upregulated.

# Example 3. SNP analysis of NOVX clones

SeqCallingTM Technology: cDNA was derived from various human samples representing multiple tissue types, normal and diseased states, physiological states, and developmental states from different donors. Samples were obtained as whole tissue, cell lines, primary cells or tissue cultured primary cells and cell lines. Cells and cell lines may have been treated with biological or chemical agents that regulate gene expression for example, growth factors, chemokines, steroids. The cDNA thus derived was then sequenced using CuraGen's proprietary SeqCalling technology. Sequence street was then sequenced using curaGen's proprietary SeqCalling technology. Sequences from all samples were evaluated manually and edited for corrections if appropriate, cDNA sequences from all samples were assembled with themselves and with public ESTs using bioinformatics programs to generate CuraGen's human SeqCalling database of SeqCalling assemblies. Each assembly contains one or more overlapping cDNA sequences derived from one or more human samples. Fragments and ESTs were included as components for an assembly when the extent of identity with another component of the assembly was at least 95% over 50 bp. Each assembly can represent a gene and/or its variants such as splice forms and/or single nucleotide polymorphisms (SNPs) and their combinations.

ಽ

2

Variant sequences are included in this application. A variant sequence can include a single nucleotide polymorphism (SNP). A SNP can, in some instances, be referred to as a "cSNP" to denote that the nucleotide sequence containing the SNP originates as a cDNA. A SNP can arise in several ways. For example, a SNP may be due to a substitution of one nucleotide for another at the polymorphic site. Such a substitution can be either a transition or a transversion. A SNP can also arise from a deletion of a nucleotide or an insertion of a nucleotide, relative to a reference allele. In this case, the polymorphic site is a site at which one allele bears a gap with respect to a particular nucleotide in another allele. SNPs occurring within genes may result in an alteration of the amino acid encoded by the gene at the position of the SNP. Intragenic SNPs may also be silent, however, in the case that a codon including a SNP encodes the same amino acid as a result of the redundancy of the genetic code. SNPs occurring outside the region of a gene, or in an intron within a gene, do not result in changes in any amino acid sequence of a protein but may result in altered regulation of the expression

52

8

엉

pattern for example, alteration in temporal expression, physiological response regulation, cell type expression regulation, intensity of expression, stability of transcribed message.

Method of novel SNP Identification: SNPs are identified by analyzing sequence assemblies using CuraGen's proprietary SNPTool algorithm. SNPTool identifies variation in 5 assemblies with the following criteria: SNPs are not analyzed within 10 base pairs on both ends of an alignment; Window size (number of bases in a view) is 10; The allowed number of mismatches in a window is 2; Minimum SNP base quality (PHRED score) is 23; Minimum number of changes to score an SNP is 2/assembly position. SNPTool analyzes the assembly and displays SNP positions, associated individual variant sequences in the assembly, the depth of the assembly at that given position, the pulative assembly allele frequency, and the SNP sequence variation. Sequence traces are then selected and brought into view for manual validation. The consensus assembly sequence is imported into CuraTools along with variant sequence changes to identify potential amino acid changes resulting from the SNP sequence variation. Comprehensive SNP data analysis is then exported into the SNPCalling database.

엉 25 8 5 of genotyping. This protocol takes double-stranded, biotinylated PCR products from genomic method dNTP excess is degraded by apyrase, which is also present in the starting reaction which results in the formation of ATP. Subsequently, the ATP accomplishes the conversion of and used as a substrate, together with adenosine 5'-phosphosulfate (APS), for ATP sulfurylase, bioluminometric assay of pyrophosphate (PPi) that is released from each dNTP upon DNA single stranded bound DNA. SNPs are characterized utilizing a technique based on an indirect Polymorphisms by Real-time Pyrophosphate DNA Sequencing. (2000). Genome Research. 10, method know as Pyrosequencing (Pyrosequencing, Westborough, MA). Detailed protocols for variants are reported. Variants are reported individually but any combination of all or a select SNP panels. The DNA and protein sequences for the novel single nucleotide polymorphic been fully automated and adapted to a 96-well format, which allows rapid screening of large mixture, so that only dNTPs are added to the template during the sequencing. The process has proportional to the number of added bases, up to about four bases. To allow processivity of the luciferin to its oxi-derivative by the action of luciferase. The ensuing light output becomes chain elongation. Following Klenow polymerase-mediated basc incorporation, PPi is released DNA samples and binds them to streptavidin beads. These beads are then denatured producing Issue 8, August. 1249-1265. In brief, Pyrosequencing is a real time primer extension process Pyrosequencing can be found in: Alderborn et al. Delermination of Single Nucleotide Method of novel SNP Confirmation: SNPs are confirmed employing a validated

subset of variants are also included. In addition, the positions of the variant bases and the variant amino acid residues are underlined.

#### Results

Variants are reported individually but any combination of all or a select subset of variants are also included as contemplated NOVX embodiments of the invention.

S

### NOV1a SNP data:

NOV1a has two SNP variants, whose variant positions for its nucleotide and amino acid sequences is numbered according to SEQ ID NOs:1 and 2, respectively. The nucleotide sequence of the NOV1a variant differs as shown in Table 67.

2

The SNP at nucleotide 746 has a putative allele frequency of 0.250.

## OTHER EMBODIMENTS

Although particular embodiments have been disclosed herein in detail, this has been done by way of example for purposes of illustration only, and is not intended to be limiting with respect to the scope of the appended claims, which follow. In particular, it is

soontemplated by the inventors that various substitutions, alterations, and modifications may be made to the invention without departing from the spirit and scope of the invention as defined by the claims. The choice of nucleic acid starting material, clone of interest, or library type is believed to be a matter of routine for a person of ordinary skill in the art with knowledge of the embodiments described herein. Other aspects, advantages, and modifications considered to be within the scope of the following claims.

WHAT IS CLAIMED IS:

- . An isolated polypeptide comprising an amino acid sequence selected from the group consisting of:
- (a) a mature form of an amino acid sequence selected from the group consisting of SEQ ID NOS:2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 27, and 29;
- (b) a variant of a mature form of an amino acid sequence selected from the group consisting of SEQ ID NOS:2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 27, and 29, wherein one or more amino acid residues in said variant differs from the amino acid sequence of said mature form, provided that said variant differs in no more than 15% of the amino acid residues from the amino acid sequence of said
- (c) an amino acid sequence selected from the group consisting SEQ ID NOS:2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 27, and 29; and
- (d) a variant of an amino acid sequence selected from the group consisting of SEQ ID NOS:2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 27, and 29, wherein one or more amino acid residues in said variant differs from the amino acid sequence of said mature form, provided that said variant differs in no more than 15% of amino acid residues from said amino acid sequence.
- The polypeptide of claim 1, wherein said polypeptide comprises the amino acid sequence of a naturally-occurring allelic variant of an amino acid sequence solected from the group consisting SEQ ID NOS:2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 27, and 29.
- The polypeptide of claim 2, wherein said allelic variant comprises an amino acid sequence that is the translation of a nucleic acid sequence differing by a single nucleotide from a nucleic acid sequence selected from the group consisting of SEQ 1D NOS:1, 3, 5, 7, 9, 11, 13, 15. 17, 19, 21, 23, 25, and 28.
- The polypeptide of claim 1, wherein the amino acid sequence of said variant comprises a conservative amino acid substitution.

- polypeptide comprising an amino acid sequence selected from the group consisting of: An isolated nucleic acid molecule comprising a nucleic acid sequence encoding a Š
- a mature form of an amino acid sequence selected from the group consisting of SEQ ID NOS:2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 27, and 29; <u>a</u>
- wherein one or more amino acid residues in said variant differs from the amino acid sequence of said mature form, provided that said variant differs in no more consisting of SEQ ID NOS:2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 27, and 29, a variant of a mature form of an amino acid sequence selected from the group than 15% of the amino acid residues from the amino acid sequence of said 3
- an amino acid sequence selected from the group consisting of SEQ ID NOS:2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 27, and 29;
- a variant of an amino acid sequence selected from the group consisting SEQ ID amino acid residues in said variant differs from the amino acid sequence of said NOS:2, 4, 6; 8, 10, 12, 14, 16, 18, 20, 22, 24, 27, and 29, wherein one or more mature form, provided that said variant differs in no more than 15% of amino acid residues from said amino acid sequence; ਉ
- a nucleic acid fragment encoding at least a portion of a polypeptide comprising an amino acid sequence chosen from the group consisting of SEQ ID NOS:2, 4, wherein one or more amino acid residues in said variant differs from the amino acid sequence of said mature form, provided that said variant differs in no more 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 27, and 29, or a variant of said polypeptide, than 15% of amino acid residues from said amino acid sequence; and e
- a nucleic acid molecule comprising the complement of (a), (b), (c), (d) or (e). 9
- The nucleic acid molecule of claim 5, wherein the nucleic acid molecule comprises the nucleotide sequence of a naturally-occurring allelic nucleic acid varianl. છ
- polypeptide comprising the amino acid sequence of a naturally-occurring polypeptide The nucleic acid molecule of claim 5, wherein the nucleic acid molecule encodes a ۲.

- single nucleotide from a nucleic acid sequence selected from the group consisting of The nucleic acid molecule of claim 5, wherein the nucleic acid molecule differs by a SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, and 28.
- The nucleic acid molecule of claim 5, wherein said nucleic acid molecule comprises a nucleotide sequence selected from the group consisting of: 9
- a nucleotide sequence selected from the group consisting of SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, and 28; <u>a</u>
- sequence selected from the group consisting of SEQ ID NOS:1, 3, 5, 7, 9, 11, a nucleotide sequence differing by one or more nucleotides from a nucleotide 13, 15, 17, 19, 21, 23, 25, and 28, provided that no more than 20% of the nucleotides differ from said nucleotide sequence; Ð
- a nucleic acid fragment of (a); and ව ව
  - a nucleic acid fragment of (b).
- under stringent conditions to a nucleotide sequence chosen from the group consisting SEQ ID NOS:1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, and 28, or a complement of The nucleic acid molecule of claim 5, wherein said nucleic acid molecule hybridizes said nucleotide sequence. <u>0</u>
- The nucleic acid molecule of claim 5, wherein the nucleic acid molecule comprises a nucleotide sequence selected from the group consisting of: ≓
- more nucleotide sequences from a coding sequence encoding said amino acid a first nucleotide sequence comprising a coding sequence differing by one or sequence in said first nucleotide sequence differ from said coding sequence; sequence, provided that no more than 20% of the nucleotides in the coding æ
- an isolated second polynucleotide that is a complement of the first oolynucleotide; and Ð
- a nucleic acid fragment of (a) or (b). ত্র
- A vector comprising the nucleic acid molecule of claim 11. 걸
- The vector of claim 12, further comprising a promoter operably-linked to said nucleic acid molecule Ξ.

297

- A cell comprising the vector of claim 12.
- 15. An antibody that binds immunospecifically to the polypeptide of claim 1.
- 16. The antibody of claim 15, wherein said antibody is a monoclonal antibody.
- 17. The antibody of claim 15, wherein the antibody is a humanized antibody.
- 18. A method for determining the presence or amount of the polypeptide of claim 1 in a sample, the method comprising:
- (a) providing the sample;
- (b) contacting the sample with an antibody that binds immunospecifically to the polypeptide; and
- (c) determining the presence or amount of antibody bound to said polypeptide, thereby determining the presence or amount of polypeptide in said sample.
- 19. A method for determining the presence or amount of the nucleic acid molecule of claim 5 in a sample, the method comprising:
- (a) providing the sample;
- ) contacting the sample with a probe that binds to said nucleic acid molecule; and
- (c) determining the presence or amount of the probe bound to said nucleic acid
- thereby determining the presence or amount of the nucleic acid molecule in said sample.
- 20. The method of claim 19 wherein presence or amount of the nucleic acid molecule is used as a marker for cell or lissue type.
- 21. The method of claim 20 wherein the coll or tissue type is cancerous.
- 22. A method of identifying an agent that binds to a polypeptide of claim 1, the method comprising:
- (a) contacting said polypeplide with said agent; and
- (b) determining whether said agent binds to said polypeptide.

- The method of claim 22 wherein the agent is a cellular receptor or a downstream
- 24. A method for identifying an agent that modulates the expression or activity of the polypeptide of claim 1, the method comprising:
- (a) providing a cell expressing said polypeplide:
- contacting the cell with said agent, and

Ē

 determining whether the agent modulates expression or activity of said polypeptide,

whereby an alteration in expression or activity of said peptide indicates said agent modulates expression or activity of said polypeptide.

- 5. A method for modulating the activity of the polypeptide of claim 1, the method comprising contacting a cell sample expressing the polypeptide of said claim with a compound that binds to said polypeptide in an amount sufficient to modulate the activity of the polypeptide.
- 26. A method of treating or preventing a NOVX-associated disorder, said method comprising administering to a subject in which such treatment or prevention is desired the polypeptide of claim 1 in an amount sufficient to treat or prevent said NOVX-associated disorder in said subject.
- The method of claim 26 wherein the disorder is selected from the group consisting of cardiomyopathy and atherosclerosis.
- The method of claim 26 wherein the disorder is related to cell signal processing and metabolic pathway modulation.
- The method of claim 26, wherein said subject is a human.

29.

30. A method of treating or preventing a NOVX-associated disorder, said method comprising administering to a subject in which such treatment or prevention is desired

the nucleic acid of claim 5 in an amount sufficient to treat or prevent said NOVX-associated disorder in said subject.

- The method of claim 30 wherein the disorder is selected from the group consisting of cardiomyopathy and atherosclerosis.
- The method of claim 30 wherein the disorder is related to cell signal processing and metabolic pathway modulation.
- 33. The method of claim 30, wherein said subject is a human.
- 34. A method of treating or preventing a NOVX-associated disorder, said method comprising administering to a subject in which such treatment or prevention is desired the antibody of claim 15 in an amount sufficient to treat or prevent said NOVX-associated disorder in said subject.
- 35. The method of claim 34 wherein the disorder is diabetes.
- The method of claim 34 wherein the disorder is related to cell signal processing and metabolic pathway modulation.
- The method of claim 34, wherein the subject is a human.
- A pharmaceutical composition comprising the polypeptide of claim 1 and a pharmaceutically-acceptable carrier.
- A pharmaceutical composition comprising the nucleic acid molecule of claim 5 and a
  pharmaceutically-acceptable carrier.
- A pharmaceutical composition comprising the antibody of claim 15 and a pharmaceutically-acceptable carrier.
- 41. A kit comprising in one or more containers, the pharmaceutical composition of claim

38

301

42. A kit comprising in one or more containers, the pharmaceutical composition of claim

39

- 43. A kit comprising in one or more containers, the pharmaceutical composition of elaim
- 40.

  44. A method for determining the presence of or predisposition to a disease associated with altered levels of the polypeptide of claim 1 in a first mammalian subject, the method
- (a) measuring the level of expression of the polypeptide in a sample from the first mammalian subject; and

comprising:

(b) comparing the amount of said polypeptide in the sample of step (a) to the amount of the polypeptide present in a control sample from a second mammalian subject known not to have, or not to be predisposed to, said disease. wherein an alteration in the expression level of the polypeptide in the first subject as compared to the control sample indicates the presence of or predisposition to said disease.

- 45. The method of claim 44 wherein the predisposition is to a cancer.
- 46. A method for determining the presence of or predisposition to a disease associated with altered levels of the nucleic acid molecule of claim 5 in a first mammalian subject, the method comprising:
- (a) measuring the amount of the nucleic acid in a sample from the first mammalian subject; and
- (b) comparing the amount of said nucleic acid in the sample of step (a) to the amount of the nucleic acid present in a control sample from a second mammalian subject known not to have or not be predisposed to, the disease; wherein an alteration in the level of the nucleic acid in the first subject as compared to the
- The method of claim 46 wherein the predisposition is to a cancer.

control sample indicates the presence of or predisposition to the disease.
